CURRENT MEDICAL LITERATURE

INDEX OF SUBJECTS

Explanation: This index refers to the titles and the subjects of original articles published in the leading medical journals of the world, including The Journal, during the past six months. The reading matter which appeared in The Journal is not indexed here, except the original articles and the abstracts of original articles. The titles of the articles and the names of the journals in which they appeared were listed weekly in the Department of Current Medical Literature, and it is to them that references are here made. The figure in parenthesis refers to the paragraph; the number following, to the page in The Journal. For instance, "Abdomen, fibroma of wall of, (45) 75," refers to page 75 of The Journal, on which is found, in paragraph numbered 45, the title of the paper and the name of the author, viz, "Fibroma of the Anterior Abdominal Wall, W. Krusen." This title is listed under the journal in which the article appeared, the *American Journal of Obstetrics*, May, 1908. When "ab" follows a page number it indicates that the article was abstracted in The Journal; for instance, "Abdomen, gunshot wounds of, (16) 1276—ab." On page 1276, paragraph 6, will be found an abstract of this article, which appeared in the *New York Medical Journal*, Sept. 26, 1908. Titles of articles which appeared originally in The Journal are indicated in the index by an asterisk (*) before the page number; for instance, "Ablatio Placentæ, *1845," refers to page 1845 of The Journal, on which is found the complete original article. The index *to authors* of all articles, both original and those listed under Current Medical Literature, appears separately on pages 2321 to 2336 of this index.

Bengal, puerperal diarrhea of, (5) 2005
Beriberi, (79) 2004
  etiology of, and presence of arsin *in rice*, (9) 2234
  laryngeal disturbances in, (54) 174
Berlin, microsporon epidemic at, (105) 358
  mortality from tuberculosis in, causes of decline of, (40) 712-ab
  postgraduate study in, (26) 866
Beurmanni, sporotrichum, epididymitis, orchitis and vaginalitis from, (43) 1737
Bichat: his life, researches and character, (63) 709, (72) 1035
Bier cup, application of, in recent empyemas, *572
  Hyperemia: See also Hyperemia constriction, Hyperemia suction, etc.
  Klapp suction method in suppurations of neck, (53) 257
  method for practitioners, (15) 795
Bile agar cultures, in diagnosis of typhoid, (95) 447
  channels and gall bladder, inflammation of, without gallstones, (96) 448—ab
  congestion of, disturbances in portal circulation from, (135) 267
  duct, common, and ampulla of Vater, melanotic sarcoma of, (106) 260—ab
  duct, common, cause of sudden fall in blood pressure while exploring, (35) 1731—ab
  duct, common, complete obstruction by melanosarcoma, (129) 78
  duct, common, consequences of stenosis or obliteration of, (131) 1013
  duct, common, melanoma of Vater's diverticulum and lower portion of, causing complete obstruction, (152) 870
  duct, common, removal from, of 2½ ounce calculus, (32) 2089
  duct, common, resection of, (142) 359
  duct, common, ruptured, operation, recovery, (54) 1469
  duct, intrapancreatic segment of, a landmark in biliary ducts, (26) 2186
  ducts and gall bladder, syphilis of, (59) 1903
  ducts, surgical anatomy of, (64) 1286—ab
  hemolytic action of, and its inhibition *by blood serum*, (45) 1464—ab
  in experimental production of colitis *in animals*, (40) 236
  media and Smith's solution, use of, (76) 1466
  pigment, determination of, and its clinical importance, (122) 359
  virulence-enhancing property of, in typhoid and colon bacilli, (68) 1738
Bilharziasis among women and girls in Egypt, (17) 1906
Biliary, surgery, (70) 792
Biliary-tract and gall bladder, pathologic anatomy of, (145) 1188
  and pancreas, jaundice due to disease of, (15) 1106
  difficulties and dangers in operations on, (59) 1035—ab
  inflammations of, medical treatment of, (3) 1900—ab
  results of operations on, at Hochenhogg's clinic, (85) 715
  results of surgery of, (162) 171
  shovel retractor for operations on, (80) 2097
  traumatisms of, operative treatment, (51) 1285—ab
Biliousness or autointoxication, (82) 1552
Bilirubin content of pneumonic sputum, (113) 717
Binders, infant, dangers and evil effects of, (11) 172—ab
Bi-nitrobenzin poisoning, chronic, unusual case of, (8) 1189
Biology, what subjects can be pracically included in year's work in? (19) 707
Bionomics of fleas, (27) 628
Birth, edema persisting since, (28) 872
Bismuth carbonate, intoxication with bismuth subnitrate and its substitution with, (123) 1042
  in diagnosis of conditions of esophagus and stomach, (16) 1283
  poisoning, (73) 1558, (4) 2234
  poisoning, fatal, (116) 2012—ab
  salts and functions of stomach, (18) 1283
  subnitrate, intoxication with, and its substitution with bismuth carbonate, (123) 1042
Bismuth subnitrate, nitrite poisoning from, (73) 1558
  vaselin paste injections, (20) 1372
Biuret test for pepsin in stomach content, (169) 87
Bladder affections, retention catheterization in, (182) 87—ab
  and prostate, cysts near, (83) 1471—ab
  and uterus, traumatic rupture of, during labor at term, *1406
  and vagina during pregnancy, histologic peculiarities of, (113) 1117
  apparatus to collect urine after operations on, (75) 1114
  carcinoma, radical treatment of, (33) 1372—ab
  carcinomatous degeneration involving one-third of, with dermoid cyst of ovary, (110) 1110
  extroversion of, implantation of ureters into rectum for, in woman, by modified Peter's operation, (9) 1820
  female, (91) 1819—ab
  exstrophy of, apparatus for compressing pelvis in Trendelenburg's operation for, (99) 358
  extirpation of, (42) 1641
  hernia, (75) 2097—ab
  impaction of pubic arch in, fractures of pelvis and femur and trauma of kidney, recovery, (87) 948—ab
  involvement, postdiphtheritic multiple neuritis with, (13) 255
  lavage, apparatus for, (70) 264
  method of dissolving foreign bodies in, (112) 717—ab
  neuroses, (68) 76—ab
  operations, simple instrument for, (111) 717
  or intestinal autoinfection with colon bacillus, (104) 1289
  or prostate, advanced cancer of, bilateral ureterostomy in, (16) 443—ab
  prolonged irrigation and drainage of, after prostatectomy, (80) 948—ab
  rupture of, traumatic, (59) 1642—ab
  sphincter, cure of insufficiency of, by drawing forward uterus, (138) 1117
  stone, and prostatectomy, (70) 258
  stone, nucleus of which was revolver bullet, (9) 951
  stone, with intermittent pneumaturia for 3 years and subsequent formation of fecal fistula, (111) 260—ab
  stone, x-ray diagnosis and treatment of, (157) 360—ab
  stones, (27) 531, (90) 1186, (75) 1642, (6) 2189
  stones, renal origin of, *885
  suture, indications and results, (46) 797
  tuberculosis, (18) 1730, (23) *1901*—ab, (70) 2003—ab
  tumors, (134) 626, (15) 2186—ab
  tumors, in children, (76) 1912—ab
  tumors, transperitoneal removal of, (41) 791—ab
  wounds, gastric and duodenal ulcers secondary to, (105) *260*—ab
Blastomyces, cases probably mycotic, but not evidently due to, *1868
Blastomycetes in blood, (139) 1744—ab
Blastomycosis, resembling bone tuberculosis, (117) 1553—ab
  systemic, etiologic, pathologic and clinical features; and coccidioidal granuloma, (17) 944
Bleaching pigmented tissues, improved method of, (125) 1282
Blepharitis, rational treatment of, (99) 1037
Blindness following injection of protargol in lachrymal sac, (101) 442
Blood affections, treatment of, and regeneration of blood, (84) 955
  alkalinity of, (52) 168
  amount of, in human beings, (68) 446—ab
  analysis in appendicitis, (8) 348—ab, (85) 625—ab, (129) 1640, (44) 1641
  and iodin, viscosity of, (53) 873—ab
  and other body fluid, sodium chlorid content of, clinical method of determination, *478
  and urine, suprarenal products in, (93) 358
  anemia from deficient production of, (46) 713
  aneurism impeding supply of, to brain and arms, (85) 2009
Blood, arterial, attempts to resuscitate animals by passing through heart and central nervous organs, (113) 2196—ab
  blastomycetes in, (139) 1744—ab
  carbon *monoxid in*, determination of, (89) 176
  cells, origin of, (127) 78
  changes in abdominal cases requiring immediate operation, (66) 1642
  circulating, multiplication of piroplasma bovis and piroplasma pithcci in, compared with piroplasma canis, (47) 1039
  clinical importance of determination of antitrypsin in, (61) 1380
  coagulating property of, importance *of proteolytic leucocyte ferment* in, (96) 2099—ab
  composition of, in relapsing fever, (125) 359
  content when water is ingested, (64) 2096
  corpuscles and histologic modes of destruction of, rôle of spleen in production of blood pigment, (27) 796
  corpuscles, bacterial agglutination of, (104) 800
  corpuscles, influence of morphin on resistance of, (100) 799
  corpuscles of foreign species, sudden death following injections of, (53) 1903—ab
  corpuscles, red, effect of heated serum on rouleaux formation of, (46) 1464
  corpuscles, red, mica plates for research on, (122) 1474—ab
  counting apparatus, devices for increasing usefulness of, (190) 171
  count, differential, in the diagnosis of empyema in children, (109) 949
  culture studies, occurrence and significance of negative results in, (37) 1902—ab
  cultures in typhoid, (33) 866—ab
  direct transfusion of, and suture of bloodvessels by vascular anastomoses, (25) 1278
  disease and sarcoma, (85) 2004—ab
  diseases, (123) 260
  diseases, transmissibility of, (103) 1740
  dust, (105) 541
  donor's, adaptability to receiver's in transfusion, (53) 947—ab
  examination, diagnosis of African tick fever from, (33) 1185—ab
  examination, in exophthalmic goiter, (68) 1286—ab
  examination in surgical diagnosis, (47) 257
  examination of, in peripheral vascular provinces with circulatory disturbances, (134) 1117—ab
  examinations, interpretation of, (12) 1639
  ferricyanid method for determining gas in, (99) 83
  findings of pernicious type in severe *anemia, *1973*
  formed elements of, influence of phosphorus intoxication on, (102) 83
  guaiac test for, (69) 714
  hematin and iron in, proportions of, (67) 2096
  importance of antitrypsin in, (55) 797
  in acetonemia, periodical in children, (112) 1289—ab
  in acromegaly, (86) 1288—ab
  in ankylostomiasis, (7) 794
  in exophthalmic goiter and thyroidism, (70) 1558—ab
  in gonorrhea, (125) 1290
  in infectious disease, leucocytic changes in, (71) 174
  in Malta fever, (154) 360
  in meningitis, (101) 177—ab
  in myxedema, (124) 359
  in pellagra, experimental, (113) 1383
  in pernicious anemia, (36) 952—ab
  in puerperal infection, (75) 82—ab, (48) 1113, (111) 1473—ab
  in splenic anemia and splenectomy, (30) 866—ab, (16) 1462
  in trypanosome infections, acidity and alkalinity of, (41) 1038—ab
  in typhoid, (105) 800
  in typhoid, determination of antigens and antibody in, (65) 1738
  in urine, determination of, by spectroscopic-chemical methods, (101) 716
  in urine, hydrogen dioxid test for, 988—ab
  leukemic, chemical composition of, (113) 1826
Blood, method for measuring clotting time of, (66) 1109
  method of expelling, from lower half of body, (113) 177—ab, (90) 1472—ab, (121) 1742—ab
  modifications in, in preventive hemostasis with Esmarch-Silvestri technic, (125) 178
  mononuclears of *guinea-pigs*, Kurloff's bodies in, and their protozoic nature, (62) 1823
  morphologic study of, at bedside, (68) 174—ab
  morphology of, in pertussis, (36) 1463—ab
  occult, in stools and stomach contents, in gastrointestinal affections, (97) 83—ab
  of hydrophobia patient, (3) 78-ab
  of miner killed in explosion in bituminous coal mine, examination for carbon monoxid in hemoglobin of, (64) 1109
  picture, neutrophile, in incipient acute appendicitis, (85) 1288—ab
  picture, neutrophile, in infectious diseases, (129) 1475
  pigment, histologic modes of destruction of blood corpuscles and rôle of spleen in production of, (27) 796
  pneumococcus in, in pulmonary tuberculosis, (60) 1823—ab
  producing organs, histologic changes in, in pernicious anemia, (92) 176
  production and artificial hemolysins, (112) 1383—ab
  production, extrauterine, (91) 176—ab
  putrefying, viscosity of, (151) 360
  regeneration, and treatment of blood affections, (84) 955
  retrogression to embryonal conditions in, (62) 174
  ring-bodies in, in anemia, (72) 174
  serum, action of drugs on, (84) 356—ab
  serum, antitrypsin and antipepsin *in, (145) 1475*
  serum, antitryptic power of, in cancer, (89) 83—ab, (63) 714
  serum, hemolytic action of bile and its inhibiton by, (45) 1464—ab
  serum, influence of on proteolytic leucocyte ferment, (103) 81
  serum in malignant disease, cytolytic factor occurring in, *915
  serum, modifications in, from heating it, (63) 446
  serum, normal, pro-infective action of, (40) 1464—ab
  serum of typhoid carriers, complement-binding substances in, (145) 86
  serum, phagocytosis in, when mixed in vitro with horse serum, (5) 951—ab
  specific gravity of, value of taking during saline transfusion in cholera, (36) 2191—ab
  stain, improved technic *for* Romanowsky, (68) 954
  stains medicolegally considered, (45) 1185
  streptococcus aggressins in, in puerperal sepsis, (89) 799
  study of, by general practitioner, (98) 1382
  transfusion, new method of, (14) 2089—ab
  transfusion of, in the transplantable lymphosarcoma of dogs, (91) 869
  treatment causing variations in calcium content of, (28) 945
  tuberculosis immune, treatment *of* tuberculosis with, (76) 1471—ab
  variations in calcium content following *therapeutic* measures, (28) 945
  vessel anastomosis by rubber tubing, (18) 1550—ab
  vessel surgery, physiologic aspects of, *1658
  vessels, action of drugs on, (65) 2003
  vessels, cerebral disease of problems and diagnosis, *179
  vessels *and organs, permanent results of transplantation of*, (79) 2194—ab
  vessels, experimental pathology of, (104) 177
  vessels, heart and lungs, diseases of, (97) 1281
  vessels, large, and diameter of heart, percussion of changes in, in fevers, (130) 1562—ab
  vessels, large, clamping of, near heart in operation for pulmonary embolism, (76) 2097—ab

Blood vessels, large, necrosis of limbs after ligation of (50) 797—ab
  vessels, pulmonary, abnormalities of, (141) 1111
  vessels, pulsating in throat, (133) 1117
  vessels, pulsating, in worms physiology of, (51) 1108
  vessels, serous coat of, compared with peritoneum, (32) 790—ab
  vessels, suture of, and direct transfusion of blood by vascular anastomosis (25) 1278
  vessels, transplantated drainage of ventricles of brain by, (38) 2095—ab
  vessels, transplantation and anastomosis of, (141) 268
  vessels, uterine and ovarian in dogs, hemorrhage following section of, and its bearing on ruptured pregnancies, (31) 1816—ab
  viscosity, *1653, (79) 1825, (65) 2096
  viscosity, changes in at high altitudes, (139) 85
  viscosity, importance of determination of, (66) 2097—ab
Blood pressure and obstetrics, (26) 945—ab
  and polycythemia, (80) 2009—ab
  apparatus for graphic registration of, (73) 1193
  arterial in surgical kidney affections and appendicitis, (65) 356
  cause of sudden fall in, while exploring common bile duct, (35) 1731—ab
  clinical estimation of, by finger and hemomanometer, (10) 1644
  factors in estimation of, *1000
  general principles regulating, (50) 873
  high arterial and retinal hemorrhages, (104) 1733—ab
  high from renal changes in hemorrhage into pons, (51) 1468
  in arteriosclerosis (27) 1550
  in brain diseases and injuries (81) 1818
  in eclampsia, (35) 256 ab
  in chronic nephritis (104) 84
  in man, its measurement and regulation, (2) 1735—ab
  in neurasthenia, (4) 626—ab
  in tuberculosis at high altitude (18) 944—ab
  increased and cerebral hemorrhage, (47) 2090—ab
  lowering reflexes from irrigation of chest in empyema, (26) 1816—ab
  measurement of comparison of technics for (78) 447
  measurement of, in chronic nephritis (68) 1911—ab
  normal and pathologic association of age and incipient cataract with *400
  obstetric importance of, and its relation to work of heart, (116) 177
  systolic and diastolic, measurement of, (98) 1041—ab
  systolic, measurement of, (46) 1285—ab
  venous, instrument for determination of (47) 1464
Body elevator and support for operations on the abdomen and trunk, *196
  production of agglutinins in, by inoculation of substances other than products of bacterial origin, (157) 870
  weight and heart weight in various animals, the ratio between (156) 870
Bolus in diphtheria (100) 176
Bone affection, Köhler's, etiology of, (125) 2197
  cysts osteitis chondromata and similar affections (80) 632
  free, plastic operations and attempts at transplantation of joints and stiffening joints (79) 1040—ab
  hyoid caries of, *1425
  infections non tuberculous, about hip joint, (14) 1184—ab
  lesion Roentgenologic discussion of, (80) 77
  marrow atrophy of, experimental production of, with typhoid toxin, (66) 174
  marrow sclerosis of, spleen as hematoplastic organ, as exemplified in case of splenomegaly with (111) 870
  neoformation of at distance from periosteum (99) [illegible]
  regeneration from periosteum (105) 77
  surgery motor fo (50) 1034
  temporal, (87) 441
Bone, temporal, surgical anatomy of, and its bearing on spread and cure of suppuration, (137) 1906
  temporal, suppuration of, (137, 139) 950
  temporal, suppuration of, treatment other than surgical, (60) 1280
  tuberculosis, (68) 948—ab
  tuberculosis blastomycosis resembling (117) 1553 ab
  tuberculosis surgical, (47) 2188
Bones and joints affections of, tuberculous origin of, in man and dog causing hypertrophy, (47) 1822
  and joints, syphilis of, (57) 947
  and joints tuberculosis of, opsonic therapy in, (32) 256
  in children undescribed affection of, (116) 1474—ab
  long, extension treatment of fractures of shaft of, (37) 1190—ab
  long, fracture of, (55) 1185—ab
  long fractures of, necessity for end to end apposition in,(31) 1737—ab
  long, hydatid disease in, (71) 1114—ab
  maxillary, compound comminuted fractures of, *1697
  metacarpal, fractures of (30) 1736
  of forearm, direct and internal splintage by operation in fractures of, (37) 1379—ab
  of leg, shortened lengthening, by operation, (42) 256
  Paget's disease of, (70) 1911
  plastic operations on, (75) 1040—ab
  supernumerary, in wrist and ankle and sesamoid bones, in Roentgen picture, (130) 85
  temporal surgery of, (139) 2198
Books, disinfection of (61) 1108—ab
Borax in epilepsy, (91) 1825
Bothriocephalus latus, (13) 73
Botryomycosis in man, (56) 81
Bougies for dilation of infundibulum (23) 1467
Boulder Lodge Sanatorium, light treatment of disease at, (9) 255
Bowel, gunshot wound causing rupture of, without damage to peritoneum, (157) 171
Bowleg, spontaneous correction of, greater tendency to, than of knock knee, (106) 77
Boy of three, ileocolitis in, complicated by tapeworm, (111) 1282
Brachial plexus, traumatic paralysis of unilateral paresis of diaphragm with involvement of sympathetic due to, (77) 1381
Brachydactylia, congenital ankylosis of fingers with (81) 1287
  hereditary, (8) 1554
Brain abscess, *667
  abscess and pyonephrosis, *756, (108) 1466
  abscess diagnosis of, (91) 632—ab
  abscess, extradural (129) 870
  abscess of otitic origin, (9) 627, (88) 793, (138) 950
  abscess, otitic, diagnosis of, (93) 2092
  abscess, partial auditory and visual aphasia with object blindness due to, (82) 869
  abscess with chronic purulent otitis media (34) 1551
  affections, fatal, without apparent lesion (91) 1559
  affections, focal localization of, importance of motor disturbances in external ocular muscles for, (84) 447—ab
  and arms, aneurism impeding supply of blood to, (85) 2009
  and eye complications of anemia and relationship to thrombosis, (26) 1378—ab
  and spinal cord ocular manifestations of organic diseases of, (97) 1643
  aneurisms of vessels of, (2) 1189
  anomalous and pathologic conditions of vascular system of, (73) 1186
  artificial hyperemia of in incipient arteriosclerosis (71) 955—ab
  blood pressure in disease and injuries of, (81) 1818
  centers for taste and smell, and uncinate group of fits *879
  complications of otitic origin (19) 531, (62) 624, (77) 625 (144) 676—ab (9) 627 (88) 793 (125) 870 (138) 950, (131) 1734, (27, 28) 1820 (88) 2092
  concussion, (24) 531—ab
  concussion contusion and compression ocular symptoms of (85) 1466
  cortex structure of (78) 2009
  diagnostic phenomenon in diseases of *461
Brain, diagnostic puncture of, (64) 714
  disease, headache of, (63) 1035—ab
  findings in infants with inherited syphilis, (80) 1912—ab
  glioma of, (8) 255
  glioma of, involving pia mater, (7) 2185
  hemorrhage, extensive, life after, *2101
  hemorrhage in, operation for, (76) 76
  hernia, anatomy of, (55) 1556
  influenza, (9) 79—ab
  inhibition of, and motor function, *183
  neuroglioma gangliocellulare of, (10) 438
  non penetrating trauma of, operation for, (34) 790—ab
  puncture, (12) 1554, (5) 1820—ab
  rheumatism of, (131) 717—ab
  sarcoma, successful removal of, in region of left sensory motor convolutions, (88) 358
  surgery (63) 630—ab
  symptoms in hydrocephalus, *1933
  syndrome cured by antisyphilitic treatment, (127) 717—ab
  syphilis, diagnosis and treatment, (97) 1036
  traumatism of, (74) 1818—ab
  tuberculosis with paralysis of both third nerves, (37) 1821
  tumor, (71) 1375—ab
  tumor, autopsy record, (14) 1032
  tumor in frontal lobes, with symptoms simulating paresis, (73) 792
  tumor in temporal lobe, *879
  tumor localized and removed, symptomatology of lesions in parietal lobe (34) 1108—ab
  tumor successful removal of, (98) 1196
  tumor, symptomatology of, (81) 1825
  tumor, three cases, *1057
  tumors, diagnosis of, (155) 86—ab
  tumors in children, (83) 82—ab
  tumors, ocular symptoms of, (85) 1036—ab
  tumors, pathology of (43) 953—ab
  tumors, surgery of, (114) 541—ab
  vascular lesions of right side, and progressive, left sided hemiplegia due to gliosis, (70) 1035—ab
  ventricles drainage of, by transplanted blood vessels, (38) 2095—ab
  ventricles, subcutaneous drainage of, in hydrocephalus, (78) 356—ab
  vessels disease of, with problems in diagnosis *179, (155) 950—ab
Branchial cleft, first, sinus of, (33) 1033—ab
Brazil climate and diseases of, (27) 712
Bread, sawdust, in treatment of habitual constipation (85) 539—ab
Breast abnormal secretion from, in non pregnant women, *1839
  cancer indications for operation (22) 1190—ab
  cancer operation and after treatment (98) 876
  cancer, permanent cure of, (58) 713—ab
  cancer of, recurrence at late period after operation for, (32) 1731—ab
  cancer treatment of, (52) 1279
  conditions that require removal of child from, (34) 167—ab
  eczema of nipple with carcinoma of, (40) 1555
  feeding importance of, for reduction of infant mortality, (107) 1473—ab

Fibroids complicating pregnancy, labor and puerperium (74) 258
  hysterectomy abdominal, for, in London (11) 443
  of uterus operative and nonoperative, (7) 1815—ab
  relation of carcinoma of uterus to, (2) 1461—ab
  uterine, showing peritheliomatous changes late recurrence after operation (12) 2190
Fibrolysin in cicatricial pyloric obstruction, (3) 1111
Fibroma, calcified, of orbit, (101) 1643
  of abdominal wall, (45) 75, (129) 1553 (126) 1742
  of skin, multiple, in pregnant woman, (99) 1876
  of trachea, (132) 78, (39) 440
  ulcerated in anterior wall of vagina, (54) 2007
Fibromata, uterine, pregnancy, complicated by, in hemiplegia, (134) 442
Fibromyoma of round ligament, (57) 1465—ab
Fibromyomata and vascular system, (45) 1379
  of uterus and anemia, *1395
Fibula and tibia, compound comminuted fracture of treatment, *2057
Filariasis as it appears in Queensland, (34) 1112
  nocturna, (55) 1642—ab
Filtering beds, properly constructed, (9) 941
Filtration system, intermittent continuous, (152) 1906
Finger, enchondroma in tendon sheath of, (24) 712
  joints, congenital familial dermatogenic contracture of (82) 1825
  plethysmography and turgosphygmography, (53) 2096—ab
Fingers congenital ankylosis of, with brachydactylia, (81) 1287
  fractured, treatment of, (80) 175
  fusion of, with hemimelia, (45) 355
  gangrene of (78) 710
  infectious ulcerations of, (61) 446—ab
First aid courses what should be taught regarding the dangers of, infectious diseases in, (67) 356—ab
  package, improved, for field, (123) 267
  packets, individual, of principal armies of world, (98) 1733
Fishberries poisoning from, used as abortifacient, (101) 2099
Fistula anal, (75) 2189
  anal, advantage of elastic ligature in cases of, (29) 1107—ab
  between lung and esophagus, (66) 1114—ab
  esophagotracheal, congenital atresia of esophagus with, etiology of, (105) 177
  in ureter, atrophy of kidney with, (67) 1739—ab
  jejunal enzymes of human pancreatic and intestinal juice obtained through, (60) 1732
  pathology of, between stomach and colon (97) 448—ab
  of labyrinth caloric nystagmus test in (108) 1389
  pancreatic secretion from and influence on it of antidiabetic diet (68) 1980—ab
  pancreatic physiology and pathology of secretion of, (81) 1559—ab
  rectovaginal, imperforate anus with, *670
  unilateral congenital, of lachrymal sac (31) 946
  ureterovaginal complete and incomplete differential diagnosis (61) 709—ab (88) 948—ab
Fistulas, diagnosis and treatment of, (60) 76—ab
Fistulous tracts tuberculous, treatment of, (68) 709—ab
Fits uncinate group of, and the cerebral centers for taste and smell, *879
Flatfoot, (33) 1551—ab
  contracted treatment of, during sleep, (118) 1827
  facts for assimilation and dissemination (11) 1815
  hyperemia in (75) 539
  value of Gleich's operation in, (54) 1 56
  shoe for, (117) 84
Flea how it clears itself of plague bacilli (28) 628—ab
  killing power of certain chemicals, (44) 1112
Fleas, bionomics of, (27) 628
  on rodents and men on Pacific Coast, *495
Flexion cause of, in hip disease, (107) 77
Flies as carriers of bacillus typhosus, (12) 1735
  as carriers of contagion in yaws, (95) 712—ab
  typhoid due to (6) 2088—ab
Florida, proliferating cestode larva in man in, (98) 1110—ab
Fly, house, as agent in dissemination of infectious diseases, (60) 1108—ab
Fluoroform treatment of whooping cough by, (136) 1734
Food adulterations and health (134) 260
  Congress, First International, impressions of, (27) 1554
  and air passages foreign bodies in, bronchoscope and esophagoscope for location and removal of, (132) 1734
  eaten too rapidly, overdistention and overwork of stomach, from (43) 713—ab
  in chronic nephritis, (104) 84
  infant reliability of sterilized and pasteurized milk as, (149) 1906
  infantile affections resulting from, (123) 1652
  inspection at ports of entry, (21) 871
  pure and drug inspections (69) 2101
  values practical application of in nutrition of children, (79) 1156—ab
Foods and medicines, proprietary, state regulation of, (13) 1111
  energy value of, (77) 1036
Foot and arms, multiple and recurring patches of gangrene on, (44) 173—ab
  backward dislocation of, and extension dressing with flexed knee, (121) 150
  clonus apparatus for automatic registration of, (126) 1914
  disabled in military service and diagnosis by skiagraph, (125) 9 0
  lipoma of, diffuse painful, (8) 1466
  perforating ulcer of, negative results of stretching nerve for, (140) 267
  tendon sheaths of, in relation to tendovaginitis and perimysitis crepitans (70) 2197
Forceps, (56) 1732
  axis traction, vs telephone and motor car, (34) 1555—ab
  high, for high transverse facial presentation, (128) 267
  laryngeal, (82) 625
  nasal septal, (96) 442
  removal of retained fetal membranes, (63) 1647
  reverse antrum, with sphenoid punch attachments *1233
  tonsil, (154) 171, *1696
Foreign bodies and cancer of intestine, (57) 2008—ab
  bronchoscope and esophagoscope for location and removal of, in air and food passages, (132) 1734
  extraction of, (8) 442
  in abdominal cavity, (28) 1033 (68) 1035
  in esophagus, (35) 1555, (126) 2197—ab
  in eye diagnosis and treatment of, (79) 141, (56) 1375
  localization of, by new method, (23) 1283
  in nose as cause of maxillary empyema, (91) 1552
  in trachea and stomach (11) 1549
  migration of, (103) 1259—ab
  of irregular shape in esophagus, extraction of, (49) 1380
  syringe for removal of, from ears, (63) 1193
  removal of, from trachea of child, (107) 1552
Formaldehyd, antiseptic and germicidal properties of, and action on toxins, (79) 1466
  derivatives, fate and actions in body *818
Fossa, iliac, method of partitioning off after complicated appendicectomy, (50) 1285—ab
Foster Milburn Co., vs Col Jack P Chinn, history of case of, (44) 1185—ab
Fowl muscles of, action of barium chlorid on, (45) 1817
Fowls, body weight and egg weights in, results of ovarian transplantation on, *1314
  Cypriote, spirochetosis of, (24) 354
Fracture and dislocation of neck at sixth cervical vertebra in man of sixty, recovery, (10) 1815
  and dislocation of second cervical vertebra (8) 2185
  and refracture of patella, treatment, (29) 1736—ab
  chauffeur's (43) 1379—ab
  Colles' malpositions of ulna in, (118) 78
  compound comminuted of tibia and fibula treatment of, *2057
  incomplete, laceration of tubercle of tibia or defective growth? (52) 1822
  isolated, of scaphoid bone, (81) 1114
  of arm above condyle treatment of, (73) 2193
  of arm, treatment of, (119) 78
  of atlas, isolated comminuted, (143) 268
  of base of skull with prolonged unconsciousness (146) 1037
  of clavicle, new dressing for, (104) 1110
  of clavicle, treatment of, (7) 2233
  of clavicle unusual (11) 791
  of distal phalanx from tearing off of extensor tendon, (60) 174
  of eminentia capitata (33) 1640
  of femoral shaft, splint for, (69) 2003
  of femoral shaft treated by open method, (68) 2003—ab
  of femur, (76) 1648
  of femur, improved Hodgen splint for, (37) 167—ab
  of femur, in new born, (15) 79—ab, (16) 711—ab
  of femur neck in adults operative treatment of (38) 2090—ab

Fracture of femur, neck in young, (76) 1114—ab
  of femur, treatment of, (113) 260, (39) 2090—ab
  of fingers, treatment of, (80) 175
  of humerus, treatment of, (35) 74—ab
  of humerus, with dislocation, operative treatment of, (33, 34) 74—ab, (58) 441, (65) 624
  of jaws, (11) 255
  of larynx, (102) 169
  of leg, treatment of, (131) 1111
  of long bones, (55) 1185—ab
  of long bones, extension treatment of, (37) 1190—ab
  of long bones, necessity for end-to-end apposition in, (31) 1737—ab
  of *metacarpal* bones, (30) 1736
  of neck of radius, (103) 1644
  of nose, depressed, operation for, (21) 1467
  of os calcis, (13) 1729—ab
  of patella, (106) 949, *1944
  of patella, treatment of, (72) 169—ab, (62) 792—ab
  of patella, ununited, comminuted, removal of bone for, (81) 533—ab
  of pelvis and femur, trauma of kidney and impaction of pubic arch in bladder, (87) 948—ab
  of radius, (99) 77—ab
  of ribs, rupture of lung, and pneumohemothorax, (34) 1378
  of skull, bursting, decompressive operations in, (30) 74
  of skull, *compound* comminuted, (102) 1643
  of skull, injuries of cranial nerves from, *271
  of spine, treatment of, (88) 351
  of tibial spine, (67) 441
  supracondyloid, *of humerus, reduction of, (40) 1372—ab*
Fractures, ancient, some lessons from, (11) 1038
  and depressed deformities of nose, treated by combined bridge and intranasal splints, (98) 1552
  and dislocations, treatment of, (106) 1650—ab
  and their consequences, operative treatment of, (80) 1040—ab
  compound comminuted, of all maxillary bones, *1697
  delayed union in, (17) 1278, (60) 1375
  extension without use of weights for, (17) 790—ab
  mobilization and massage in, (11) 1554—ab
  obscure, diagnosed by x-ray, (26) 439, (21) 622, (24) 790—ab, (19) 1462, (21) 1640
  of bones of forearm, direct and internal splintage by operation in, (37) 1379—ab
  of femoral shaft, recent, operative treatment of, (39) 1372—ab
  of ribs, treatment of complications from injury of lungs in, (60) 1556
  of vertebræ, (112) 2195
  operative treatment of, (61) 713
  severe traumatisms and, (55) 257—ab
  strain, of knee, (44) 791
  treatment of, (15) 172, (116) 793
  treatment of, by direct internal splintage, (37) 1379—ab, (143) 1734, (27) 1736
  x-ray diagnosis of, (1) 1105—ab, (54) 1465
Frambesia tropica, (116) 260
Frame, metal, for veil to wear while operating, (119) 1827
France, admission of foreign students to medical schools, (71) 82
Francois de Paris, miracles at tomb of (14) 255—ab
Fraternal spirit, (103) 169
Fremitus, vocal, in croupous pneumonia, (97) 1559
French and German for medical students, (11) 1466
  clinics in neurology and psychiatry, (51) 1817
  surgical congress, twenty-first, transactions of, (52) 2192
  surgical congress, verdict of, on facial nuralgia, (47) 1909—ab
Fresh-air methods at home for consumptives, (14) 260
  school, (140) 260
  treatment in home as applied to pediatrics, *1505
Freund's operation: See Chondrotomy
Friction sounds and râles, physical and clinical study of, (134) 634
Frontal presentation, influence of gravity on production of, (61) 1113
Frontal sinus disease, conservative treatment of, (73) 258
Fruits, food value of, (42) 1191—ab
Fulguration: See also Cancer: Lightning treatment of
  of vital organs, (69) 875
Function, chemical regulation of, (140) 626
Fundus, capacity of extension of, and peristaltic movements of stomach, (64) 174
  desirability of ophthalmoscopic examination of, while still possible in senile cataract (91) 2004—ab
Fungus coccidioides, (37) 531

G

Galactosuria, alimentary, in jaundice, (59) 1193
Galalith *intestinal button, (61) 356*
Gall-bladder and bile channels, inflammation of, without gallstones (96) 448—ab
  and bile ducts, syphilis *of,* (59) 1903
  and biliary passages, pathologic anatomy of, (145) 1188
  cholecystostomy with recovery of pure culture of typhoid bacilli from, (37) 1640
  congenital absence of, (36) 439
  diseases, treatment of, (93) 2004
  drainage of, (95) 352
  drainage of, in chronic pancreatitis, (39) 2187
  empyema of, with stone, following *typhoid, (160) 1188*
  empyematous, primary sarcoma of, (56) 1556
  gangrene of, (37) 790
  pedicle of, torsion of, (81) 356 (52) 1192
  surgery of, (131) 626, (70) 792, (147) 1188
  surgical affections of, (71) 1109—ab
Gallop-rhythm of heart, (42) 167—ab
Gallstone affections, benign stenosis of pylorus simulating, (68) 1114
  affections, familial, (50) 174
  disease, (76) 441
  disease, importance of early surgical treatment, (37) 1551
  disease, ischochymia simulating, (60) 441—ab
  disease, medical treatment of, (21) 866
  disease, pancreatitis and, *377
  disease, symptoms of, (146) 1188
  disease, treatment of, (110) 442, (69) 709
  empyema of gall bladder with, following typhoid, (160) 1188
  factors, (28) 623
  ileus, (94) 1471—ab
  ileus, operation, recovery, (5) 1282
  operations, concrements *forming* on threads after, (98) 358
  surgery, (18) 354
Gallstones, (144) 171
  and pancreatic diabetes, (23) 2234—ab
  as etiologic factor in diabetes, (29) 623
  differential diagnosis of, (19) 1372
  inflammation of gall bladder and bile channels without, (96) 488—ab
  medical treatment of, (84) 1819
  prevention of, and cholecystitis, (9) 2088
  regurgitation a symptom of, (22) 1640
  surgical treatment of, (87) 1740—ab
Galvanotropism in bacteria, (74) 350
Games, educative aspect of, (38) 1821
Ganglia, pathogenesis of, (45) 707—ab
Ganglion, Gasserian severe trigeminal neuralgia successfully treated by excision of, (52) 1468
  Gasserian, surgery of, (128) 352—ab
  petrosal, herpes of membrani tympani due to zosteroid affection of, (35) 1108
Ganglioneuroma, (56) 713—ab
Gangrene and empyema of lung complicating typhoid in child, (61) 257
  angiosclerotic, treatment by arteriovenous intubation, (71) 631—ab
  diabetic, amputation in, (13) 789—ab
  extensive enterectomy for, (3) 1189
  in strangulated hernia, treatment of, (7) 171—ab
  limited annular, of small intestine invagination *of,* vs. resection, *472
Gangrene of extremities after pneumonia, (20) 952—ab
  of extremities complicating typhoid, (165) 87—ab
  of extremities in infant, (48) 867—ab
  of fingers, (78) 710
  of gall bladder, (37) 790
  of limbs, after ligation of large trunk vessels, (50) 797—ab
  of puerperal uterus, (45) 1279
  of rectum, apparently spontaneous, (57) 1380
  of skin in rheumatoid scarlatina, (28) 1554
  of skin, postscarlatinal, (62) 714

Lab and pepsin in fundus and pylorus of human stomach, and relations between action of pepsin and concentration of acid, (99) 1041
Labels plain on germ friends (19) 439
Labial, pelvic and abdominal tumor, (7) 2234
Labor and pregnancy complicated by rectal cancer, (42) 1284
  and pregnancy following ventrosuspension of uterus for retrodisplacements (39) 707—ab
  and pregnancy, surgical necessities during (91) 625—ab
  and puerperium fibroids complicating (74) 258
  anesthesia in, (29) 2006
  at term, traumatic rupture of uterus and bladder during *1406
  death of mature fetus in, (92) 77—ab
  dry, uterine action in, (51) 2090
  graduated in pulmonary tuberculosis (68) 1904
  hour glass contraction of uterus during (47) 1279
  in contracted pelvis hebosteotomy vs other procedures in management of (25) 2001—ab
  in occipito posterior positions, (163) 1189
  in private practice (63) 1552
  induced and nephrectomy for pyonephrosis and renal calculi, (18) 1639
  induction of, (116) 1111
  management of to prevent dystocia, (39) 1279—ab
  management of in minor degrees of pelvic contraction indications for abdominal Cesarean section (46) 167—ab
  methods of operation in obstructed (96) 1037—ab
  missed (15) 1377
  morbid dread of as indication for abortion (106) 84
  normal (61) 1552 (66) 1818
  normal, preparation for, (83, 84) 2189—ab
  ovariotomy performed during, (84) 1739 (93) 2094—ab
  pregnancy and puerperium after ventrofixation, (3) 1553—ab
  pregnancy and puerperium kidney disease during, (101) 1281—ab
  premature, and vaginal Cesarean section, for induction of, indications and contra-indications, (30) 1278
  scopolamin morphin anesthesia in, (73) 175—ab (11) 1377
  surgical necessities following, (92) 625—ab
  third stage of, treatment, (86) 1875
Laboratories, medical, visit to some abroad, (24) 945
Laboratory *feeding modern* and range of resources it provides (80) 1376—ab
  limitations of, in medical colleges, (23) 256
  method Sydenham method greater than, (21) 4462—ab
Laboratory methods use of, by general practitioner, (120) 534
  methods value of modern, for practitioner, (104) 169—ab
  state, aids of, in diagnosis and treatment (100) 2005
  worker, and specialist, relation of general practitioner to, (54) 257
Laboring classes obstetric service for and relation of midwife to it in Michigan, (105) 171
Labyrinth acute suppuration of, following otitis media; operation, recovery, (90) 2092
  deafness with tone island, (86) 441
  destruction of, for severe vertigo and tinnitus, (31) 1378
  fistula of, caloric nystagmus test in (108) 1393
  reactions of, and their significance in diagnosis of suppurative labyrinthitis, *1754
  non acoustic functions of, (87) 2092
  non suppurative involvement of, in mumps *1961
  suppuration, diagnosis and treatment of, (141) 950
Labyrinthitis, infective, treatment of after 15 years' experience, (136) 950
  suppurative, reactions of labyrinth and their significance in diagnosis of, *1754
Laceration, circular, of vagina, (137) 1117
  complete perineal, secondary repair of, (70) 2091—ab
  isolated, of mesentery after contusion of abdomen (72) 1648
  perineal (143) 1282
Lachrymal obstruction, (35) 629
  sac extirpation of (7) 442, (86) 1904, (121) 1905
  stricture recurrent traumatic erosion of cornea due to (118) 1905
Lactation abnormal, *1839
  and menstruation, (84) 82—ab
  long *495
  long retained capacity for, in non nursing mothers, (85) 82—ab
Lactic acid bacilli and soured milk in forms of chronic ill health, (4) 870
  cultures in nose, throat and ear work (18) 348
  growth of in stomach content, (101) 876
Laity and physician (75) 948
Lameness intermittent (37) 256
Laminectomy explorative, and circumscribed serous meningitis, (77) 2009
Lamp, quartz, white and blue light of (150) 535
Lancet student's number, (1) 1111—ab
Lanosum, frequency of, in man and in dog, (28) 712
Laparotomies after treatment of, *874 (4) 1371
  after treatment of, care of wounds and preliminary treatment, (132) 1820
  allowing patients to get up early after, (119) 1561—ab, (131) 2197
  during pregnancy, (58) 1375
  50 for various conditions, (84) 1466
  100 without death in country practice (49) 1874—ab
  preparation of patients for, (84) 176—ab
  remote pain following, (98) 1187—ab
Laparotomy, care of patients, after, *834 (4) 1271
  adhesions after, (161) 86
  double for ruptured bile duct, (54) 1409
  early exploratory, in diagnosis of diseases of upper abdominal digestive tract (164) 171
  new dressing for (104) 1110
  phlebitis following (103) 1110
  plea for early exploratory in gastric diseases of doubtful nature, (73) 624—ab
  preparatory and after treatment of, *739
  radical for carcinoma of cervix uteri (6) 1554—ab
  35 cases of extrauterine pregnancy without death, dealt with by, (5) 1068
  to hasten recovery after, by allowing patients to leave bed early, (57) 355—ab
Larvae, dipterous, infection of man by (37) 2002
Laryngeal complications in typhoid, (69) 1994
  crises and paresis of abductor of vocal cords, *815
  diphtheria, (127) 270, (114) 1185

Neck and face, spasmodic movements of, elements of diagnosis between, (20) 1730
  branchiogenic multilocular cysts of, (56) 1380
  deformities of, (128) 1734
  extirpation of tuberculous glands of, explanation of exophthalmos, tachycardia and tremor following, (27) 2186
  injury of nerves during extirpation of glands in, (59) 713—ab
  fracture and dislocation of, at sixth cervical vertebra in man of 60, recovery, (10) 1815
  multilocular cyst of, in infant, (42) 445
  neoplasms of, operation for (23) 531
  tuberculous glands in, embolic tuberculous pneumonia following massage of, (90) 1559
Necresis, chloroform, of liver, (35) 1463—ab
  of fat tissue, subcutaneous, (140) 1743
  of limbs, frequency of, after ligation of large trunk vessels, (50) 797—ab
  of myomata during pregnancy, (78) 1470
  phosphorus, treatment of, (54) 355—ab
  progressive, of costal cartilages, (44) 2095—ab
  subcutaneous, of fat tissue, (130) 1474—ab
Needles, extraction of, (120) 1042—ab
Negro consumptives, (84) 533—ab, (121) 793
  outlook of, for health, (85) 533—ab
  pure-blooded, unusual degree of myopia in, (104) 146
Neoplasms: See also Tumors
  abdominal, differential leucocytic estimation in diagnosis of, (76) 1904
  active, non-relationship of, to prognosis in malignant disease, *910
  malignant, epidermal fibrils in classification of, (101) 869
  melanotic, (142) 1734
  new, of animals, appearance of heteroplastic tumors in transplantations of, (5) 865
  new intrathoracic, (1) 870—ab
  of neck, operation for, (23) 531
Nephrectomy and nephrotomy, indications for, (18) 1554
  case requiring immediate, *1780
  for pyonephrosis and renal calculi, (18) 1639
  subsequent, on account of hemorrhage, after nephrolithotomy for renal calculi, (8) 951
  vaginoureterostomy after, for pyonephrosis due to sigmate constriction of ureter, (16) 1278
Nephritis, acute, (103) 352
  acute, in childhood, (41) 867—ab
  acute, in scarlet fever treated by spartein sulphate, (28) 707
  acute parenchymatous, (72) 948
  acute syphilitic, (17) 166
  as complication and sequel of measles, (116) 1282
  chronic, blood pressure and influence of food in, (104) 84
  chronic, blood pressure and its measurement in, (68) 1911—ab
  chronic and suprarenal lesions, (23) 2089—ab
  chronic, etiology of, (27) 348—ab
  chronic, experimental, (96) 869
  chronic interstitial, (170) 1189
  chronic interstitial, arterial changes in, (65) 1732
Nephritis, chronic interstitial, and recurring paralysis, (169) 171
  chronic interstitial, etiology and pathology of, including urinary findings, (66) 1732
  chronic, subtemporal decompression in, for neuroretinal lesion, with uremia, (31) 1902—ab
  chronic, serotherapy of, (59) 1823—ab
  chronic, treatment, (69) 1642—ab
  congenital, (6) 2185—ab
  decapsulation of kidneys for, (176) 950, (96) 1740—ab, (56) 1909—ab
  experimental, glomerular lesion of, (3) 255
  experimental, nephrotoxic substances in serum of animals with, (45) 1903—ab
  experimental, salt metabolism in, (146) 1475
  hemorrhagic, following scarlet fever, *1410
  in infancy, (37) 1467
  interstitial, (20) 348
  of pregnancy, suparenal capsules in, (51) 81—ab
  operative treatment of, (50) 1374—ab
  sclerous atrophic, of tuberculous origin, (57) 1286—ab
  secondary, in transplacental typhoid infection, (49) 1817—ab
  serotherapy of, (57) 1738—ab, (59) 1823—ab
Nephrolithiasis, (112) 260—ab
  symptomatology of, (56) 1286—ab
Nephrolithotomy for renal calculi: subsequent nephrectomy on account of hemorrhage, (8) 951
Nephropexy, new technic for, (59) 441—ab, *54
Nephrotomy, experimental studies on human kidney of consequences of, (79) 1287
Nephrotoxic substances, presence of, in serum of animals with experimental nephritis, (45) 1903—ab
Nephroureterectomy, complete, for renal tuberculosis in women, *459
Nerve, abducent, paralysis of, with otitis media, (123) 1282
  anastomosis in infantile paralysis, (16) 348—ab
  area, mental, and grayness of hair, (14) 443
  atrophy, optic, infrequent type of, *290
  auditory, division of, for painful tinnitus, (26) 1645—ab
  cells, Edinger's theory of using-up of, (123) 1914
  circumflex, inflammation of, (17) 255
  condition, velocity of, temperature coefficient of, (73) 350—ab
  disease, organic, and heart affections, (39) 1468
  endings, action of curara and physostigmin on, (44) 1817
  facial, surgery of, (134) 950
  facio-hypoglossal, anastomcsis of, *455
  great splanchnic, experiments on nature of glycogenolytic fibers in, (54) 1108
  great splanchnic, influence of, stimulation of, on disappearance of glycogen from liver, (55) 1108
  injuries of upper extremity, diagnosis and electrical treatment of, (22) 1283
  median, immediate results in implantation of, (98) 2092
  nasal, resection of, intractable hay fever and paroxysmal coryza cured by, (4) 171—ab
  nucleus icterus of infants, (95) 799—ab
  optic, changes in multiple sclerosis, *120
  optic, differential diagnosis of affections of, *483
  optic, importance of disturbances in, in incipient multiple sclerosis, (70) 1470—ab
  optic, indirect injuries of, (62) 948—ab
  sedative, (58) 168
  sixth cranial, paralysis of, in aural disease, (20) 1467
  splanchnic, structure of lobule of liver under influence of, (130) 1043
  strain as etiologic factor in nervous affections, (99) 632—ab
  stretching of, negative results of, for perforating ulcer of foot, (140) 267
  trunks, large, adiposis dolorosa with involvement of, (17) 2088
  ulnar, occupation neuritis of deep palmar branch of, (88) 2004—ab
  ulnar, recurrent dislocation of, (38) 1372—ab
Nerves and arteries, neoplastic infection of, cancer and cirrhosis of liver with, (128) 1914
Nerves and tobacco, (72) 76
  cervical, section of posterior primary divisions of, in spasmodic torticollis, (14) 1554
  ciliary, angioma of orbit, with invasion of globe along, (117) 1905
  cranial, injuries of, from fractures of skull, *271
  injury of, during extirpation of glands in neck, (59) 713—ab
  peripheral, diagnosis of injuries of, from those of spinal cord, (154) 1734
  recurrent laryngeal, paralysis of, of peripheral origin, (15) 438—ab, (83) 2092
  seventh cervical, injury to posterior roots of, followed by posterior column degenerations, (90) 1376
  suture of, (54) 264—ab, (34) 866
  sympathetic and autonomous, antagonism between as affecting drug influence on internal secretion, (175) 87
  third, complete paralysis of, tuberculosis of brain with, (37) 1821
  to excite glands for renal secretion, probable existence of, (67) 1039
  treatment of paralysis by plastic operations on, (107) 633—ab
Nervous affections among poor of Rome, (139) 718
  affections, nerve strain as etiologic factor in, (99) 632—ab
  affections, traumatic, treatment of, (99) 1382—ab
  affections, toxic, following house epidemic of diphtheria, (80) 1470
  and mental diseases, hydrotherapy in, (148) 1906
  and mental diseases in general practice, (175) 171
  and mental disorders from alcohol, (93) 1466
  disease, prostate as factor in, (21) 2089—ab
  diseases, organic and functional, differentiation of, (125) 260
  diseases, static electricity in, (70) 1465
  disorders in Colorado, (119) 1644
  disorders, psychic treatment of, (105) 442
  disturbances of arms in arteriosclerosis, (121) 2197—ab
  patients, bath treatment at Mt. Clemens for, (108) 442
  symptoms, functional, estimation of, (153) 1734
  symptoms produced by malaria, (19) 1906
  systems and diseases of mind, pelvic diseases and, (97) 1904—ab

  relation of, to administration of justice, (20) 866
  relation of, to mental healing systems and methods, (96) 710—ab
  responsibility of, for future of child with adenoids and impaired hearing, (42) 1374—ab
  tracheal tube with device to protect him against coughed out material, (74) 1287
Physician, role of, in producing or maintaining imaginary maladies, (47) 1374—ab
  vacation of, (5) 530
  what manufacturing druggist does for, (75) 1904
  when shall he distrust his own judgment in surgery, (62) 868-ab
  wife of, (97) 1466
Physicians and public affairs, (87) 710—ab
  are they justified in taking pay from manufacturing chemists for scientific tests of pharmaceutic preparations? (65) 1648—ab, (105) 2011—ab
  Dickens' and things medical, (80) 2189
  in Colorado for tuberculosis, (115) 1644
  must be sociologists, (76) 1732—ab
  need of more intimate knowledge of U. S. Pharmacopeia and National Formulary among, *2018
  of Samuel Johnson and his court, (145) 78
  of to-day and to-morrow, (94) 1733 —ab
  overproduction of, (69) 1185—ab
  responsibility of, for use of nostrums, *2022
  should they dispense? (80) 533
Physico-chemical properties, chemical constitution and pharmacodynamic action, (85) 793
Physics, what subjects can be practically included in year's work in? (19) 707
Physiologic actions, temperature coefficient of velocities of, (49) 1108
  assay of nitroglycerin tablets, digitalin tablets and fluidextract of ergot, *2130
Physiology and chemical pathology of pancreas in pancreatitis, (21) 2234—ab
  and pathology of emotions: physical basis of mental etiology, (8) 865
  and pathology of gastric secretions, (28) 2089
  and pathology of play of pupils, (62) 954
  and pathologic physiology of arrest of postpartum hemorrhage, (82) 447—ab
  comparative, of invertebrate heart, (51) 1108
  of circulation, practical aspects of, (37) 440
  of digestive system, (73) 2004—ab
  of heart contractions, (71) 539—ab
  of pulsating blood vessels in worms, (51) 1108
  of purin metabolism, (24) 1038
  of respiratory organs, (96) 1560 —ab
  pathologic, importance of proteolytic leucocyte ferment in, (96) 2099—ab
  relation of, to physics and chemistry, (9) 1283
  study of by general practitioner, (161) 78
  when should it be taught at college, (78) 76
Physiotherapeutics in chronic diseases, (67) 76
  in rheumatism, (100) 77
Physique, national and military service, (8) 1111
Physostigmin and curara, action of, on muscles, (44) 1817
Pia arachnoid, osseous plaques of, and pain in acromegaly, (91) 1376 —ab
  mater, glioma of brain involving, (7) 2185
Picric acid in trachoma, (142) 268
Pigment, biliary, determination of, and its clinical importance, (122) 359
Pigmentation, after prolonged administration of silver preparations, (125) 634
  local, in tuberculosis, 309—ab
Pilocarpin in strychnin poisoning, (129) 793
Pin imbedded in vein 4 years, *1509
Pipettes, simple and efficient device for filling and emptying, *756
Piroplasma bovis and piroplasma pithеci in circulating blood, mode of multiplication of, compared with that of piroplasma canis, (47) 1039
  canis, morphology and life history of, (42) 1038—ab
  pitheci and piroplasma bovis in circulating blood compared with that of piroplasma canis, mode of multiplication of, (47) 1039
v. Pirquet's Cutaneous Reaction: See Tuberculin Skin Reaction.
Pituitary and suprarenal bodies, inhibition of pancreatic activity by, extracts of, (38) 1463—ab
  body, active principle of, and diuretic action of adrenalin, *1849
  body, changes in, after removal of thyroid, (18) 1111
  body, probable tumor of, with optic atrophy following premature menopause (179) 171
  extracts, inhibition of pancreatic activity by, (43) 2002
Pityriasis rubra, diagnosis and treatment of, (125) 1043—ab
  versicolor, tropical forms of, (116) 1188
Placenta and membranes involved in fetal ichthyosis, (37) 1816
  blood, negative results of injections of, in carcinoma, (54) 797
  formation of, (62) 1738
  function of, (95) 2011—ab
  juice, isolated surviving dog kidneys flushed with, (136) 359
  normally implanted, intrauterine hemorrhage during pregnancy and from premature separation of, (50) 1551
  normally located, prolapse of, (110) 359
  normally situated, premature detachment of, *1845
  prævia, air embolism with (123) 1561—ab
  prævia, danger with, of natural straining to aid delivery, and extraperitoneal selection of uterus as means to reduce it, (112) 1651 —ab
  prævia, metreurynter for, (101) 632-ab
  prævia, treatment of, (21) 531 (59) 2193—ab
  prævia, version with, advantages of water bag over, (122) 1827—ab
  premature separation of, cause of, (16) 73—ab, (18) 1815
  syncytioma or chorioepithelioma of, (29) 167—ab
  syphilitic, spirochæta pallida in, (82) 2004—ab
  toxicology of, (55) 1647—ab
  transmission of B. typhosus in, (52) 532—ab
  triplet pregnancy and site of, (91) 956
  tumor, (56) 1113
  weight of, in relation to new-born child, (114) 78—ab
Plague, (122) 1644
  are domestic animals of India affected by? (25) 628
  bacilli, how flea clears itself of, (28) 628—ab
  bacillus, differential diagnosis of, (30) 628
  bacillus, preservation of, in body of bedbug, (51) 445
  bacteriology and pathology of, (68) 1818
  early diagnosis of, (32) 1555—ab
  great black, (117) 1037
  how it is spreading in Venezuela and Trinidad, (17) 706
  human, septicemia in, experiments on infectivity of excreta, (26) 628—ab
  in Algeria and Tunis in 1907, (60) 1469—ab
  in California and antiplague campaign, *1010
  insects in epidemiology of, (24) 628—ab
  measures against, underlying principles of, (70) 1185
  mode of spread and prevention of, (1) 944, (45) 1112
  preventers, cats as, (8) 1820—ab
  prophylaxis at Rio de Janeiro (32) 2094
  seasonal prevalence of, in India, (29) 628
  spots, municipal, duty of city toward (65) 76
Plants and health of man, chemistry and effects of bituminous coal smoke on, (8) 1815—ab
  dermatitis from, (137) 85
Plaques, osseous, of pia arachnoid and pain in acromegaly, (91) 1376—ab
Plasma cells and endometritis, importance of, in inflammation, (132) 359
  individual, (9) 710
Plaster-of-Paris in surgery, (170) 950
  jacket, sling for application of, (112) 1819
Plessimeter and percussion hammer for threshold percussion of heart, (89) 876
Plethysmogram, absolute, (109) 1289 —ab
Pleura and lung, reactions of surface of, (67) 82
  attempt to prevent adhesion of, after inflammation, (9) 1644—ab
Pleura, endothelioma of, (3) 2000 (77) 1381
  primary tumor of, (121) 634
  sound, treatment of operative pneumothorax in, (46) 2192—ab
Pleural cavities, drainage of, double empyema with, (29) 1462
  cavity, diagnosis of pus in, (115) 2026
  reflexes, (28) 1107
Pleurisy and pulmonary tuberculosis, (9) 166
  paravertebral area of dulness in, (98) 1472—ab
  traumatic pulsating, (30) 623
Pleuritic effusions, pressure in, (69) 174—ab
Pleuropneumonia, acute leucocytic, with extensive fibrinous plugs visible to naked eye in enlarged lymphatics, (24) 536
Plexus, brachial, paralysis of, and involvement of sympathetic, unilateral paresis of diaphragm from, (77) 1381
  solar, pathologic anataomy of, in consumptives, (49) 538
Pneumatic cabinet, affections in which it is indicated, (86) 265 —ab
Pneumaturia, intermittent, for 3 years, stone in bladder with, and subsequent formation of fecal fistula, (111) 260—ab
Pneumococci phagocytability of, in sputum in pneumonia, (27) 256
Pneumococcus arthritis, (77) 2091
  cultures and antiserum, injection of, for corneal ulcers, (101) 541
  in blood in pulmonary tuberculosis, (60) 1823—ab
  infection and mixed streptococcus of orbit and adjacent sinuses, (111) 1905—ab
  infection, opsonins and antiphagins in, (62) 1039
  infection, parotitis from, (130) 178 —ab
  meningitis as direct result of severe trauma of skull five years before, (101) 1826
  peritonitis due to, (29) 1190
  peritonitis due to, in children, (36) 1467
  serum, Römer's in croupous pneumonia, (89) 1740
  serum treatment of infecting corneal ulcer, (92) 1115
  stomach affection, (80) 875—ab
Pneumonia, (35) 1185, (149) 1188, (119) 1466
  abortive, (117) 1289
  acute, striæ atrophicæ as sequel of, (23) 1190—ab
  and influenza, relation of anticyclonic weather to prevalence of, on northern hemisphere, *660
  brief, (91) 1740
  croupous, leucocytes with Sudan-staining granules in, (98) 956
  croupous, meningism and meningoencephalitis in, (105) 1473—ab
  croupous, recurrences of, (110) 1561 —ab
  croupous, Römer's pneumococcus serum in, (89) 1740, (107) 1826
  croupous, serumtherapy of, (118) 2196
  croupous, vocal fremitus in, (97) 1559
  diagnostic importance of composition of urine in, (109) 877—ab
  digitalis in, *2214
  double septic, and double empyema, case with, (29) 1462
  embolic tuberculous, following massage of tuberculous glands in neck, (90) 1559
  epidemic, (117) 1914
  gangrene of extremities after, (20) 952—ab
  in childhood, (63) 168, (26) 872 —ab, (12) 951
  in infancy, diagnosis of, *285
  in infants, ambulatory treatment of, *286
  infection, and prophylaxis by cytocera (118) 1560
  influenzal, and influenza, (23) 1816 —ab
  lobar, and bronchopneumonia, symptomatology and diagnosis of, in children, (46) 623
  lobar, diagnostic value of sense of weight in affected side, (24) 2186 —ab
  lobar, pathology and treatment of, (45) 946
  lobar, uncomplicated, treatment of, (37) 2191
  metabolism of salt in, (70) 446—ab
  plus yellow atrophy of liver in girl of 10, (100) 266
  on Isthmus of Panama, (10) 1371 —ab

Pneumonia, specific skin eruption in, (16) 2190—ab
  sputum, bilirubin content of, (113) 717
  sputum, pneumococci in, phagocytability of, (27) 256
  treated by continuous inhalation of oxygen, (21) 712—ab
  treatment of, (90) 77, (21) 790—ab, (120) 1111
  types of, with inflammation of adenoids, (7) 1276
Pneumonokoniosis, etiology and prevention of, (17) 1038
Pneumohemothorax, rupture of lung, and fracture of ribs, (34) 1378
Pneumopleuritis followed by pulmonary abscess, (61) 1642
Pneumothorax, (78) 869—ab, (32) 1378
  artificially induced, influence of, on tuberculous lung, (66) 1558—ab, (47) 2095, (85) 2098)—ab
  artificially induced, indications and results, (42) 2095
  chronic, (124) 2197
  operative, treatment of, in sound pleura, (46) 2192—ab
  traumatic, *1971
  value of Sauerbruch negative pressure procedure in prevention of, *808
Podophyllin and calomel habit, (122) 793
Poehl's principles and preparations, (122) 1290
Poison, nerve, specific, negative food value of alcohol and its action as, (118) 634
Poisoning, alcoholic and metallic, causing neuroses, (186) 951
  and abortion by yew, (109) 1741—ab
  apomorphin, and relations between retching and paralysis of muscles, (83) 1381—ab
  atoxyl, pathology of, (67) 1193—ab
  belladonna, *1696
  bi-nitrobenzin, chronic, (8) 1189
  bismuth, (4) 2234
  bismuth, fatal, (116) 2012—ab
  chloroform, (76) 1642
  cantharides, acute, (8) 1282
  from fishberries used as abortifacient, (101) 2099
  homatropin, by instillation, (100) 442
  hydrazine pathologic anatomy of, (151) 870
  industrial phospho-oxychlorid gas, (101) 1289
  lead, cause of, in tinning metals, (27) 2191—ab
  lead, curiosities of, (126) 442
  lead, diagnosis and prophylaxis of, (139) 267
  meat, (65) 954—ab
  mercury bichlorid, pericarditis in course of, (65) 1039—ab
  morphin, industrial, (88) 2010—ab
  nitrite, from bismuth subnitrate, (73) 1558
  oxalic acid, (71) 1738
  phosphorus, (102) 83, (137) 1474
  resorcin, from external application, (102) 358—ab
  tea and coffee, (46) 349
  veronal, acute, symptomatology, prognosis and therapy of, (87) 265—ab
Poisons, various bacterial, behavior of human skin in response to, (128) 359
Police power of state, sanitary power as, (52) 2188
Polioencephalitis, infantile, (52) 1552
  superior, with autopsy, (38) 256
  syphilitic, (36) 2094
Poliomyelitis, acute, epidemiology of, (40) 167—ab
  acute, following tonsillitis, (4) 1549
  anterior, (43) 2090—ab
  anterior, cerebrospinal fluid in, (153) 870
  anterior, acute, (22) 80, (4) 1183—ab, (85) 1643, (13) 706
  anterior, acute, in adult, (14) 706
  anterior, acute, disease of primary motor neurons causing clinical picture of, result of poisoning by potassium cyanid, (71) 792
  early orthopedic treatment in, necessity for, (119) 1553—ab
  in infancy, muscular dystrophy following, (116) 949
Pollinosis or hay fever, (157) 950
Polyarthritis, recurring tuberculous, (112) 800—ab
Polyclinic, 500 B. C., represented on Greek vase, (72) 82
Polycythemia, *1230, (122) 1652—ab
  and blood pressure, (80) 2009—ab
  with cyanosis, *1777
  with and without enlargement of spleen, (93) 632
Polygraph, inky, (12) 172
Polymyositis, acute, (105) 1289
Polyneuritis, generalized, *cases of*, *28
Polyp formation, rhinedema with, (118) 1037
  secretion in extensive polyposis of colon and rectum and action of purgative, (97) 1041
Polyposis of colon and rectum, extensive, fermentative power of polypus secretion in, and action of purgative, (97) 1041
Polyps in stomach, (100) 448—ab
  multiple, of intestine, healing intussusception in, (35) 1640
Polyuria, essential, improved by abstinence from salt, (69) 82
Pons, hemorrhage into, renal changes in, with consequent high blood pressure, (51) 1468
Poor-law *medical service*, reformed, voluntary hospital and, (10) 261
Poor of London, dental needs of, (16) 261
  of Rome, nervous affections among, (139) 718
Portwine *marks and hypertrichosis*, involving both sides of face, removed by x-rays, (38) 873
Portal vein, thrombosis in, (103) 266
Portio vaginalis, transplantation of epithelium of vagina to cure erosions in, (140) 1117
Porto Rico as a field for research in *tropical medicine*, (16) 166
Postgraduate instruction in pediatrics, need of, (43) 867—ab
  study in Berlin, (26) 866
  study in Europe, (110) 1466, (99) 2092
Potassium cyanid, biochemical and anatomic changes induced in dogs by, (11) 348
  cyanid, disease of primary motor neurons causing clinical picture of acute anterior poliomyelitis, result of, poisoning by, (71) 792
  iodid, action of, (167) 87
  iodid, effect of, on activity of ptyalin, (62) 350—ab
  iodid in suppuration in nasal accessory cavities, (74) 1558
  oxalate, neutral, in phlegmons, adenitis, and white swelling, (111) 2099—ab
Pott's-disease, (70) 441
  appliance for reducing hump in, (64) 446
Poverty and tuberculosis, (21) 2001
Practice, acquiring, (89) 710—ab
  contract, in Germany, (73) 1375
  general, importance of autopsies in, (55) 2090
  general, mental and nervous diseases in, (175) 171
  general, vaccines in, (4) 1466—ab
  general, vaginal Cesarean section in, (65) 264—ab
  medical, interrupted currents in, (15) 1283
  medical, tact in, (60) 168
Practitioner, country, the average, *shall he testify before our juries* as medical expert? (92) 1819—ab
  general, and deaf mutism, (36) 1736
  general, and x-ray treatment, (97) 540—ab
  general, artificial infant feeding for, (40) 1816
  general, attitude of, toward eyestrain, (24) 1278
  general, clinical examination of *urine and gastric juice* by, (5) 1734
  general, clinical types of eclampsia as viewed by specialist for benefit of, (37) 349
  general, his need of bacteriology, (123) 793
  general, *immediate* treatment of serious ocular conditions frequently first seen by, (2) 789—ab
  general, necessity of his knowing when an operation should be done, and of surgeon being conservative as to operation, (131) 1820
  general, obstetrical work from standpoint of, (40) 1108
  general, rise of, (17) 2006
  general, study of blood by, (98) 1382
  general, study of pediatrics by, (99) 949
  general, study of physiology by, (161) 78
  general, treatment of acute appendicitis by, (4) 1734
  general, treatment of negligent speech by, (7) 789
  general, use of laboratory methods by, (104) 169—ab, (120) 534
Practitioners, Bier's method for, (15) 795
  general, ophthalmology for, *1833
Pragmatism and medicine, (113) 626
Precancerous morbid states, (141) 797—ab
Precipitin reaction in syphilis and *general paralysis*, (72) 356
Predisposition, constitutional of lymphatics, to disease, (107) 177—ab
  hereditary, *1221
Pregnancies, multiple, in double uteri, (50) 2002
Pregnancy, abdominal, (112) 359, (115) 1117, (124) 1377, (65) 1903, (129) 1906—ab
  abdominal secondary, with living child at term, (145) 268
  abdominal ectopic, of seventeen months' duration, (128) 1906
  affections of optic nerve in, (101) 877—ab
  albuminuria and eclampsia, parathyroid treatment of, (119) 1651—ab
  albuminuria in, (53) 867
  amaurosis in, (118) 177—ab
  and appendicitis, (97) 358, *1310, (30) 2237
  and childbirth, and axial torsion of large intestine, (116) 1117
  and childbirth with congenital mitral stenosis, (30) 712—ab
  and diabetes, (63) 1113—ab
  and early infancy, syphilis in, (51) 1279
  and gonorrhea, (133) 442
  and heart disease, (43) 1279—ab
  and labor complicated by rectal cancer, (42) 1284
  and labor following ventrosuspension of uterus for retrodisplacements, (39) 707—ab
  and labor, surgical necessities during, (91) 625—ab
  and larynx, (92) 716—ab
  and ovulation, forensic aspects of, (78) 1558
  and pernicious anemia, (38) 623—ab
  and puerperium, appendicitis in, (62) 630
  and puerperium, prognostic value of nuclear count in, (49) 867—ab
  and puerperium, sudden death during, (155) 1037
  at nine years of age, (48) 440
  autotoxemia of, (61) 2091
  causes of peritonitis during, (13) 443
  chorea during, (39) 265—ab
  complicated by malformation of vagina and uterus, (93) 1643
  complicated by tuberculosis, (23) 439, (18) 622
  complicated by uterine cancer, (90) 1825
  complicated by uterine fibromata in a hemiplegic, (134) 442
  complicating thrombosis of superior longitudinal and lateral sinuses, *997
  computation of conception, menstruation and duration of, (108) 1041
  concealed hemorrhage in, contrasted with extrauterine pregnancy, (30) 1107
  conservatism in surgery of uterine adnexa for preservation of possibility of, (66) 1465—ab
  dermoid cyst removed without interrupting, (27) 1372
  duration of, (74) 82, (61) 2192
  extrauterine, (21, 26) 167, (59) 168—ab, (112) 359, (117) 534, (32, 33, 34, 37) 623, (36) 623—ab, *840, (153) 1037, (73) 1109, (115) 1117, (39) 1284—ab, (116, 124) 1377, (15) 1729—ab, (65) 1903, (128, 129) 1906—ab, (66) 2003, (20) 2089, (95) 2195—ab, (19) 2236—ab
  extrauterine and early abortion, differentiatial diagnosis, (32) 2186
  extrauterine, and hypoplasia of tubes, (138) 2198
  extrauterine, at term, (54) 532
  extrauterine, at term, with healthy child, (145) 268, (29) 712—ab
  extrauterine, beyond full term, (33) 1462
  extrauterine, can operation be done for, during shock? (73) 2009—ab
  extrauterine, concealed hemorrhage in pregnancy contrasted with, (30) 1107
  extrauterine, dealt with by abdominal section without death, 35 cases of, (5) 1038
  extrauterine, *diagnosis of*, (79) 1552
  extrauterine, early, anatomy and histology of, (39) 1284—ab
  extrauterine, early diagnosis of, (59) 168—ab, (79) 351—ab, (55) 532, (63) 792
  extrauterine, immediate vs. delayed operation for, (38) 707—ab
Pregnancy, extrauterine, intra-abdominal hemorrhage due to deferred operation for, (47) 707—ab
  extrauterine, intra-abdominal hemorrhage due to, time to operate in, (35) 623—ab, (46) 707—ab, (32, 33, 34, 37) 623 (31) 2002—ab
  extrauterine, on goldfields, (12) 1189
  extrauterine, procedure suitable for cases of in which fetus in living, (57) 1375
  extrauterine, terminated, treatment of, (92) 169—ab
  extrauterine, treatment of early cases of, (97) 949
  extrauterine, when shall we operate? *1767
  eye complications of, *204, (101) 877—ab
  heart disease and tuberculosis in relation to, (79)—2091
  hemorrhages of, (134) 1282
  histologic pecularities of vagina and bladder during, (113) 1117
  inflammation in and around cervix uteri in, (95) 1195—ab
  intrauterine and coincident tubal, (15) 1729—ab

Joseph Ambrosia Jerger, M.D., Waterloo, Iowa, to Grace Frith-Hagans, M.D., of Chicago, November 17.

Thomas Dundon Collins, M.D., to Miss Honora Helena Driscoll, both of Ballston Spa, N. Y., November 4.

H. H. Howlett, M.D., Washington, D. C., to Miss Lina Charleton Walker, at Richmond, Va., November 6.

John Sedgwick Andrews, M.D., Orange, Va., to Miss Margaret Janvier Cooper, of New Castle, Del., October 28.

William Meredith Smith, M.D., Frederick, Md., to Miss Theresa Jamison Fitzsimmons, at Frederick, November 4.

Charles Walter Delaney, M.D., Altoona, Pa., to Miss Elda O. Teeter of Waterside, Pa., at New York City, November 5.

Jesse Strauss Heiman, M.D., Syracuse, N. Y., to Miss Louise Rachael Henry of Winchester, Va., at Baltimore, November 4.

William Minor Bryan, M.D., P. H. and M.-H. Service, New Orleans Quarantine, to Miss Henrietta Kemp White, of Locust Grove, Charlottesville, Va., November 4.

Deaths

Walter Robarts Gillette, M.D. College of Physicians and Surgeons, New York, 1863; a member of the Medical Society of the State of New York and New York Academy of Medicine; assistant surgeon in the Army during the Civil War, and for thirteen years thereafter surgeon to the New York postoffice; at one time consulting physician to Bellevue Hospital and St. Francis hospitals and the Manhattan State Hospital for the Insane; for thirty years an official, and for twelve years vice-president of the Mutual Life Insurance Company; died in Roosevelt Hospital, New York City, November 7, eleven days after an operation for cancer of the intestine, aged 68.

Emil G. Rehfuss, M.D. University of Pennsylvania, Philadelphia, 1884; a member of the American Medical Association; an ophthalmologist of repute; assistant to Dr. Turnbull and later chief of the eye, ear and nose clinic at the German Hospital, Philadelphia; for fifteen years attending ophthalmologist, and later consulting ophthalmologist to St. Agnes' Hospital; died in Philadelphia, October 31, *from influenza, aged 47.*

George W. Bowen, M.D. University of Michigan, Ann Arbor, 1860; a pioneer practitioner of the Maumee Valley; surgeon of the Fourth and Sixteenth Michigan Volunteer Infantry and the Fifth U. S. Cavalry during the Civil War; police surgeon of Toledo, physician of Lucas County, and physician to the Isolation Hospital; died at his home in Toledo, Ohio, November 4, from heart disease, aged 70.

Azel Ames, M.D. Harvard Medical School, Boston, 1871; of Chelsea, Mass.; a member of the Association of Military Surgeons of the United States; and a veteran of the Civil and Spanish-American wars; an officer in the United States service in Porto Rico and the Philippine Islands; well known as a surgeon and a sanitarian; a member of the State Legislature in 1878; died at the State Hospital, Danvers, Mass., November 12, aged 63.

Amos H. Caffee, of Carthage, Mo.; assistant surgeon of the First Arkansas Cavalry and the Fourteenth Kansas Infantry during the Civil War; and since that time a resident of Carthage; twice mayor of the city; and in 1880 treasurer of Jasper County; president of the Central National Bank and of the Carthage Stone Company; died at his home, October 23, from uremia, aged 74.

Walter J. Corcoran, M.D. College of Physicians and Surgeons, New York City, 1882; a member of the American Medical Association, Brooklyn Pathological Society, and president of the Brooklyn Gynecological Society in 1905; gynecologist to St. Mary's Hospital and St. Mary's Maternity, Brooklyn; died at his home in Brooklyn, November 5, from heart disease, aged 52.

Charles Ross Parke, M.D. University of Pennsylvania, Philadelphia, 1847; a surgeon in the Russian Army during the Crimean war; for many years a practitioner of Bloomington, Ill.; and from 1880-1903, chief of staff of St. Joseph's Hospital; one of the founders of the Illinois State Medical Society; died at the home of his daughter in Louisville, November 6, from cerebral hemorrhage, aged 85.

John R. Cook, M.D. Jefferson Medical College, Philadelphia, 1884; a member of the American Medical Association; honorary member of the Royal Gynecological Society, London; formerly president of the Cook Hospital and Training School, Fairmont, W. Va.; died at his home in Fairmont, November 9, from septicemia, due to an operation wound, aged 45.

Con W. Gatch, M.D. Cincinnati College of Medicine and Surgery, 1892; a member of the American Medical Association; secretary of the Miami Valley Medical Association; coroner of Clermont county, Ohio; health officer and for several terms mayor of Milford; surgeon to the C. M. & L. Traction Company; died at his home in Milford, November 5, aged 52.

Samuel George Renshaw, M.D. Dartmouth Medical School, Hanover, N. H., 1852; one of the best known and beloved physicians of New Orleans; a surgeon in the service of Emperor Maximilian, and later in the United States Army during and after the Civil War; died at St. Bernard Home, November 9, as the result of a fall a few weeks before, aged 79.

Philip Hamilton Sellew, M.D. Jefferson Medical College, 1890; a member of the Connecticut State Medical Society; for twelve years a practitioner of Salisbury, Conn.; for eight years a member of the local board of U. S. pension examining surgeons; died at his home in Westfield, Mass., October 31, from acute nephritis, aged 46.

George H. Bean, M.D. Physio-Medical Institute, Cincinnati, 1876; a member of the American Medical Association; a veteran of the Civil War; for 20 years a member of the Meigs County, Ohio, board of U. S. pension examiners; died at his home in Rutland, November 2, after an operation for cholelithiasis, aged 67.

Arthur G. Randolph, M.D. Rush Medical College, Chicago, 1899; a member of the Missouri State Medical Association; formerly surgeon to the Missouri Lumber and Mining Company, Grandin; and medical examiner for the C. B. & Q. Railway; died at his home in Kansas City, Mo., November 8, aged 32.

John E. Harris, M.D. Louisville Medical College, 1870; a member of the Indiana State Medical Association; and a member of the board of pension examining surgeons; for two years city editor of the Louisville *Evening Post*; died at his home in Bloomington, Ind., November 5, from nephritis, aged 61.

Charles A. Veith, M.D. University of Pennsylvania, Philadelphia, 1895; Johns Hopkins University, Baltimore, 1897; for a time deputy coroner of Schuylkill County, Pa.; formerly surgeon to the Pottsville (Pa.) Hospital; died at his home in Pottsville, from heart disease, November 5, aged 34.

Frederick H. Wells, M.D. Syracuse (N. Y.) University, 1883; a member of the American Medical Association and a specialist on diseases of the eye, ear, nose and throat, of Grand Junction, Colo.; died in St. Joseph's Hospital, Denver, November 5, from meningitis, following an infection of the face, aged 47.

William Hill Grafton, M.D. University of Maryland, Baltimore, 1849; one of the proprietors of the *West Coast Magazine*, Los Angeles; for more than forty years a practitioner of Iowa; and for two years quarantine officer at Baltimore; died at his home in Los Angeles, November 8, aged 80.

Nathaniel S. Robinson, M.D. Harvard Medical School Boston, 1852; for fifty years a practitioner of Neenah, Wis., and representative from that district in 1875; said to have been the oldest practitioner of the Fox River Valley; died at his home in Neenah, November 5, from senile debility, aged 81.

Clayton Glanville Coleman, M.D. Medical College of Virginia, Richmond, 1859; of Richmond, Va.; surgeon of the Twenty-fourth Virginia Infantry, C. S. A., during the Civil War; died in St. Vincent's Infirmary, Little Rock, Ark., October 7, from cerebral hemorrhage, aged 68.

Samuel W. Boynton, M.D. Eclectic Medical Institute, Cincinnati, 1859; University of Louisville, Ky., 1868; for many years a member of the board of U. S. pension examining surgeons in Cincinnati and Louisville; died suddenly at his home in San Antonio, Texas, October 31, aged 73.

Thomas H. Vernon, M.D. University of Edinburgh, Scotland, 1873; Royal College of Surgeons, Dublin, Ireland, 1877; formerly secretary of the state medical society and president of the Vernon County Medical Society; died at his home in Hillsboro, Wis., November 9, aged 55.

Francis E. Potter, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1881; Kentucky School of Medicine, Louisville, 1883; of Corning, Iowa; a member of the Iowa State Medical Society; was killed by the overturning of his automobile, near Corning, November 9, aged 52.

Samuel Smith Troy, M.D. Rush Medical College, Chicago, 1866; a veteran of the Civil War; and for more than 40 years a practitioner of Chickasaw and adjoining counties in Iowa; died at his home in Waterloo, November 8, from cerebral hemorrhage, aged 76.

Frederick Wright Simpson, M.D. Cooper Medical College, San Francisco, 1894; for several years a surgeon on transpacific steamers; and later a practitioner of Pueblo, Colo.; died at the home of his parents in St. Paul, Minn.; November 8, from tuberculosis, aged 34.

Daniel Winans Smith, M.D. New York University, New York City, 1856; a member of the American Medical Association; for more than fifty years a practitioner of Newark, N. J.; died at his home in that city, November 10, from senile debility, aged 75.

George William Tyner, M.D. University of Bishop's College, Montreal, 1902; of Kingston, Ont.; formerly of Norfolk, Va.; was killed by the overturning of an automobile while making a professional call at night at Tipton, Ont., recently, aged 31.

John A. Barksdale, M.D. Medical College of the State of South Carolina, Charleston, 1847; one of the oldest and most beloved practitioners of Laurens County, S. C.; died at his home in Laurens, November 6, from senile debility, aged 81.

William A. McCamly, M.D. Tulane University, New Orleans, 1869; a member of the American Medical Association; local surgeon for the Southern Pacific Railroad at Wharton, Texas; died in a sanitarium in San Antonio, November 2, aged 59.

Charles M. Ross, M.D. Missouri Medical College, St. Louis, 1891; of Tahlequah, Okla.; a member of the Missouri State Medical Association; was found dead November 3, near Tahlequah, from contact with a "live" electric wire, aged 40.

Joseph F. Dicus, M.D. Rush Medical College, Chicago, 1880; of Streator, Ill.; a member of the American Medical Association; died in St. Mary's Hospital, Streator, November 1, a week after an operation for appendicitis, aged 56.

Anton Coe, M.D. George Washington University, Washington, D. C., 1888; of Washington, D. C.; a member of the American Medical Association; died in the New Haven (Conn.) Hospital, from pneumonia, November 5.

John Joseph O'Neill, M.D. Syracuse (N. Y.) University, 1908; an interne in a hospital of Syracuse; died in the dispensary of the institution November 4, from accidental poisoning by cyanid of potassium, aged 23.

Charles A. Brown, M.D. Baltimore Medical College, 1895; a member of the American Medical Association; and a village trustee of Ludlow, Vt.; died suddenly at his home, November 2, from heart disease, aged 49.

William Newton Graham, M.D. Missouri Medical College, St. Louis, for a long time business manager of the Sedalia (Mo.) *Evening Sentinel*; died in Excelsior Springs, Mo., October 28, from diabetes, aged 59.

Arch R. Hagey, M.D. University of Pennsylvania, Philadelphia, 1901; of Hastings, Pa., formerly of Martinsburg; died from nephritis, October 30, in the University of Pennsylvania Hospital, Philadelphia.

Brown Colley, M.D. Jefferson Medical College, Philadelphia, 1897; a member of the American Medical Association; was found dead from heart disease in his office in Dunbar, Pa., November 1, aged 40.

Carman Champion Stokes, M.D. Cincinnati College of Medicine and Surgery, 1874; a member of the American Medical Association; died at his home in Rushsylvania, Ohio, November 9, aged 59.

Lloyd T. Macgill, Sr., M.D. Baltimore Medical College, 1851; of Frederick, Md.; died in the Frederick City Hospital, October 29, from septicemia following a surgical operation, aged 79.

George H. Graham, M.D. University of Bishop's College, Montreal, 1868; formerly of Wenatchee, Wash.; died in his apartments in Olympia, Wash., from pneumonia, October 31, aged 61.

Bennett Perry Alston, M.D. University of Maryland, Baltimore, 1868; a member of the Medical Society of the State of North Carolina; died at his home in Henderson, October 31, aged 62.

Oliver Leach Bradford, M.D. Trinity Medical College, Toronto, 1861; Homeopathic Hospital College, Cleveland, 1861; died at his home in Fitchburg, Mass., November 3, from cardiac asthma.

Richard N. Hewitt, M.D. University of Pennsylvania, Philadelphia, 1849; a member of the Medical Society of Virginia; died suddenly at his home in Evington, November 8, aged 84.

Orrel C. Curtis, M.D. Albany (N. Y.) Medical College, 1905; formerly of South Egremont, Mass.; died at the home of a relative in Bristol, Wis., recently, from tuberculosis, aged 27.

Alexander A. Hendrix, M.D. University of Tennessee, Nashville, 1878; a member of the Kentucky State Medical Association; died at his home in Crofton, Ky., November 9, aged 78.

Alfred Hadley Lindley, an eclectic practitioner of Los Angeles, formerly of Chicago; died at the Sea Side Hospital, Long Beach, Cal., October 18, from cerebral hemorrhage, aged 64.

Thomas Boyd Meacham, M.D. Medical College of the State of South Carolina, Charleston, 1861; a Confederate veteran; died at his home in Fort Mill, S. C., October 25, aged 72.

James D. F. Dudley, M.D. Medical School of Maine, Brunswick, 1873; died suddenly at a banquet in Arkansas City, Kan., November 2, from cerebral hemorrhage, aged 53.

Charles Edwin Parent, M.D. University of Bishop's College, Montreal, 1885; of San Francisco; died in the French Hospital in that city, October 29, from diabetes, aged 45.

Justin Allen, M.D. Harvard Medical School, Boston, 1856; a member of the Massachusetts Medical Society; died at his home in Pittsfield, Mass., November 6, aged 82.

Nelson B. Covert, M.D. Cleveland Homeopathic Medical College, 1862; an ophthalmologist of Geneva, N. Y.; died in Atlantic City, N. J., November 7, aged 68.

William A. J. Brown, M.D. Eclectic Medical Institute, Cincinnati, 1889; died suddenly at his home in Elkins, W. Va., November 5, from heart disease, aged 50.

John Harper, M.D. Cincinnati College of Medicine and Surgery, 1863; died at his home in Mount Vernon, Ind., October 19, from cerebral hemorrhage, aged 82.

Howard L. Power, M.D. Rush Medical College, 1888; formerly of Brower, Ore.; died in Marlin, Texas, October 23, from typhoid fever, aged 46.

Davies Coxe, M.D. University of Virginia, Charlottesville, 1884; of New York City; died in Dresden, Saxony, November 7, from diabetes, aged 47.

Edmund W. Fall, M.D. Bennett Medical College, Chicago, 1888; of Aurora, Neb.; died at Hot Springs, Ark., September 30, from nephritis, aged 58.

James T. Allen, M.D. Missouri Medical College, St. Louis, 1856; a pioneer settler of Gallatin, Mo.; died at his home in that place, November 6.

John Wellesley Sill (license, Mass., 1894) of Worcester, Mass.; died at the Worcester Home Farm October 31, from senile debility, aged 82.

Edwin Posey West, M.D. University of Georgia, Augusta, 1870; died at his home in Clarksville, Ga.; October 23, from mastoiditis, aged 71.

R. A. J. McFerrin (License, Tenn., 1889); a Confederate veteran, died at his home in Oliver Springs, Tenn., July 4, from heart disease.

Robert L. Wall, M.D. Missouri Medical College, St. Louis, 1890; of Tulsa, Okla.; formerly of Leeton, Mo.; died in Denver, October 25, from tuberculosis.

Franklin E. Butler, M.D. New Orleans School of Medicine, 1870; died suddenly at his home in Smithdale, Miss., November 1, from pneumonia, aged 59.

William H. McElroy, M.D. Bellevue Hospital Medical College, New York, 1881; of Houston, Texas; died in Chicago, November 1.

William H. Grominger, M.D. Pennsylvania Medical College, Gettysburg, 1848; died at his home in Philadelphia, May 6, aged 84.

J. P. Hill, M.D. Memphis (Tenn.) Hospital Medical College, 1901; of Poplarville, Miss.; died in Hattiesburg, Miss., October 31.

Philander P. Outland, M.D. Eclectic Medical Institute, Cincinnati, 1881; of Zanesfield, Ohio; died November 5, aged 57.

J. B. Reynolds, M.D. Atlanta (Ga.) Medical College, 1878; died at his home in Lumber City, Ga., November 4.

Society Proceedings

COMING MEETINGS.

Southern Surgical and Gynec. Assn., St. Louis, Dec. 15-17.
Western Surgical and Gynec. Assn., Minneapolis, Dec. 29-30.
American Assn. of Anatomists, Baltimore, Dec. 29-31.

THE SOUTHERN MEDICAL ASSOCIATION.

Second Annual Meeting, held at Atlanta, Ga., Nov. 10-12, 1908.

The President, Dr. B. L. Wyman, Birmingham, Ala., in the Chair.

Addresses of welcome were delivered by Hon. Hoke Smith, Governor of Georgia, and Dr. J. C. Olmstead, of Atlanta. The response was by Dr. G. C. Savage, Nashville, Tenn.

President's Address.

Dr. B. L. Wyman: This organization is no longer an experiment; I believe that it will develop into one of the strongest bodies in the country. Until recently the South has not kept pace with the East and West in medical progress. Owing to the unwieldy size of the American Medical Association, and to the fact that many Southern physicians could not attend its sessions, there has been for several years a need for an association, without legislative functions, whose aim should be the study of the disease peculiar to this section of the country. The aims of the association are the encouragement of scientific endeavor and the fostering of cordial relations between the members of the profession in this territory. I recommend that immediate steps be taken to establish a journal of the Southern Medical Association. Some of the problems that have to be dealt with in the South are: malaria, yellow fever and tuberculosis—especially among the negroes. County and state sanatoria for tuberculosis should be established. The chief menace to health in the South is the negro race, and negroes should be taught by the medical profession and the leaders of their race how to live properly, so that they will not so easily become a prey to disease. When the Panama Canal is completed the South will be open to new dangers, not only yellow fever, but cholera and bubonic plague.

Annual Oration: Limitations of Laboratory Work.

Dr. H. F. Harris, Atlanta: The general accentuation and widespread adoption of laboratory methods as aids in the diagnosis and treatment of disease, along with the all but universal ignorance of the general practitioner concerning them, has and still leads to much unfortunate misunderstanding. The attitude of the profession toward the laboratory man is closely akin to that of the general public toward physicians. It is curious that the intelligent physician, with his eyes wide open, will repeat the error of the layman. Laboratory work is often entrusted to young and inexperienced men, and to add to the unreliability of such examinations the laboratory man is often given no information whatever concerning the patient. A great part of our work requires expert interpretation, and laboratory results, even when accurate, are but links in the chain that go to make up the proper diagnosis. As a nation we seem to lack the artistic temperament that is necessary to do really original work. Almost without exception we content ourselves with blindly accepting the results of European investigators. To remedy these evils, the laboratory man should be careful and accurate and always give the clinician his honest opinion. The clinician should remember that practically every laboratory report requires intelligent interpretation, and that he must not expect absolute results. He should never fail to send with his specimen all possible information respecting it and the patient.

Problems in Medicine Which Affect the Prosperity of the South.

Dr. Seale Harris, Mobile, Ala.: The physicians of the South have to deal not only with the problems which are present in other parts of the country, but because of climatic and other conditions, with diseases which are peculiar to the section and which affect Southern prosperity. The principal of these are yellow fever, malaria, uncinariasis and pellagra. The health of the negro is another important question. The future of the South depends largely on the solution of these problems. If the Southern states can be freed from these diseases, if the poor whites and negroes of the South can be made stronger physically and morally and become efficient laborers, capital and capitalists will pour into this section to develop our magnificent resources. Prove that yellow fever and malaria are forever stamped from the South, and our prosperity will amaze the world.

Tincture Veratrum Viride (Norwood).

Dr. J. S. Todd, Atlanta, Ga.: This drug, at one time one of the most used, has now fallen into disfavor, especially in the North. Norwood's tincture was the only preparation used in the South, and the usual dose was one and a half minims, or three drops, generally at three-hour intervals. The doses recommended in modern books on materia medica vary from five to thirty minims. Morphin hypodermically is a perfect antidote. Veratrum viride does not cut short pneumonia, typhoid, or any other disease, but it still has its uses. It is not only a cardiac depressant, but a vasodilator. Given in the doses mentioned it does not produce any unpleasant effects, and the pulse can be kept at about 65 or 70 and soft. In the treatment of puerpural eclampsia five-minim doses may be given, hypodermatically, repeated hourly, if necessary. My principal employment of this drug now is in the treatment of certain heart diseases and all troubles in which there is increased blood pressure. It may be combined with digitalis, squills, strychnin and other drugs when indicated.

(To be continued.)

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirty-fourth Annual Meeting, held at Louisville, Ky., Oct. 13-15, 1908.

(Concluded from page 1725.)

Incidence and Differential Diagnosis of Gall-Bladder Disease and Gastric Ulcer.

Dr. J. A. Lichty, Pittsburg, Pa., discussed gall-bladder disease and gastric ulcer in detail and concluded his paper as follows: (1) The coincidence of independent gall-bladder trouble and gastric ulcer is rather rare; only 1 in 321 cases of my series. (2) Gastric ulcer with its complications can easily cause an interference with the function of the gall bladder and duct to such an extent as to produce definite gall-bladder pathology. (3) Gall-bladder disease with its complications may cause such a disturbance of gastric function as to simulate, if not actually cause, gastric ulcer. (4) While a combination of these two lesions may produce a complexity of symptoms, which makes a definite diagnosis impossible, the indications for operative interference are usually so definite that to disregard them would be disastrous to the patient.

Syphilitic Crises Simulating Surgical Emergencies.

Dr. M. A. Austin, Anderson, Ind.: The external evidence of syphilis most frequently resembles the slowly growing tumors, especially of bone, but these should give little trouble in their diagnosis. The abdominal crises may simulate a number of organic diseases. In three of my cases, one simulated gallstones, another renal colic and a third obstruction of the bowel. The various manifestations of syphilitic disease of the spinal cord are frequently overlooked. Syphilis is not a rare disease in any community; 80 per cent. of the cases are said to result from innocent infection.

Differentiation of Oft-Recurring Gastric Pains from Gallstone and Other Visceral Pains.

Dr. N. Rosewater, Cleveland, Ohio: Nearly all pains of the digestive organs occur during functional activity, while those due to gallstones, visceral and other causes are independent of the digestive periods. By giving nutritive enemata for periods of one, two or more weeks, we can put the digestive functions of the stomach and duodenum at rest for so long a period that such pains as would occur during this resting period can scarcely be attributed to gastroduodenal function, but rather to independent causes. In this way we eliminate from consideration the digestive function entirely by this gastric rest test.

Systemic Effects of Chronic Infections of the Throat and Nose.

DR. F. G. STUBBS, Chicago: In view of the fact that so many systemic diseases are infectious in origin, the atrium of infection assumes a large place in the prophylactic and hygienic treatment. The nose and throat from their anatomic location at the beginning of the alimentary and respiratory tracts, and because of diverticula, such as the sinuses and tonsillar crypts, offer a large field for local and general infection. In the nose infection is due less to the direct absorption of bacteria and toxins than to the fact that the discharges carry these into the respiratory and alimentary tracts. Pure cultures of pneumococci, streptococci and meningococci have been obtained in suppurative sinus discharges. Diseased tonsils and adenoids are responsible for a large percentage of systemic effects, particularly tuberculosis and acute articular rheumatism.

Autogenous Bacterial Vaccines.

DR. OSCAR BERGHAUSEN, Cincinnati: Bacterial injections are of distinct therapeutic value. In most cases the improvement is a gradual one, although marked at the start. As in all branches of therapeutics, negative as well as positive results will be obtained. He who wishes results must follow the methods of Wright, including a careful bacteriologic analysis in each case, the preparation of an autogenous vaccine in most cases, and a careful consideration of the clinical symptoms. The opsonic index, although it may only register one phase of immunity, can be of distinct value, especially in mixed infections.

Differential Diagnosis of Mediastinal Sarcoma.

DR. R. H. BABCOCK, Chicago: This case is reported not because of the difficulty attending its diagnosis, but because it was mistaken for either pulmonary tuberculosis or pulmonary syphilis. The patient was a young man of 27, who when seen was suffering from orthopnea, anasarca, and slight cough, with scanty mucous sputum. Chancre had been contracted three years before and mercury had been used in such doses that its physiologic effects were produced nine months prior to my visit. These symptoms had been mistaken for the secondary manifestations of lues, and they, together with the discovery by *x*-ray of a shadow at the right of the sternum, had seemed to confirm the supposition that the pressure symptoms subsequently developed were due to gumma in the right lung. Physical examination, however, revealed unmistakable signs of intrathoracic pressure with displacement of the heart, right-sided hydrothorax and anasarca. Enlarged cervical and axillary lymph nodes were also detected. The subjective and objective symptoms were so plainly unlike those of consumption of the lung or of gumma of that organ that I had no hesitation in diagnosing a tumor, probably sarcoma, of the mediastinum. A subsequent postmortem established the correctness of the *intra vitam* diagnosis.

Hysterical and Neurasthenic Conditions Following Accidents.

DR. B. F. TURNER, Memphis: A plaintiff in an action for damages following an accident need not necessarily be considered as perpetrating a fraud because physical disability can not be proven. To assume the grave responsibility of expert witness demands extraordinary skill, knowledge and experience, as well as a finely adjusted judicial temperament. It is no part of the office of the medical expert witness to support either side of the case. Rather than to run the risk of appearing ridiculous in the eyes of his fellow practitioners, the conscientious physician will decline an attractive fee and refuse to appear in a rôle for which his daily walk and well-established reputation appears to fit him but poorly.

Surgery of Venereal Stricture of the Rectum.

DR. GEORGE B. EVANS, Dayton, Ohio: Venereal disease of the rectum constitutes an affection which has been mastered by neither the syphilographer nor the proctologist. The former is not familiar with the armamentarium for rectal exploration, and the latter is not thoroughly familiar with venereal diseases. The manifestations of syphilis escape the former because they are often removed from the field of vision; while the attention of the latter is called to the fact because pain exists in the rectum. Two propositions confront us: First, is this form of stricture of the rectum a local manifestation, or is it due to primary sore? Second, is it the result of secondary or tertiary syphilis, or rather a constitutional infection followed by chronic inflammation and infiltration? According to an able author, it is due to the rectum becoming inoculated through the secretions from the sores on the vulva, thus giving rise to chancroidal ulcers; these ulcers become cicatrized and constriction takes place. Again, the presence of chancroids at the orifice of the vagina, or about the anus gives rise to an inflammation of the areolar tissue surrounding the lower portion of the gut, and by the effusion of inflammatory material at certain points, giving rise to constriction either in this way alone or by directly producing inflammation and ulceration of the mucus coat of the bowel. I have seen many cases of chancroid of the vulva extending down and involving the anus, which were filthy in the extreme, but stricture of the rectum did not exist. If chancroidal virus were carried into the rectum, every prostitute would have stricture of the rectum. I believe that secondary induration of the rectum following a chancroid of the anus can occur. This induration may be followed by a chronic inflammation and ulceration and develop cicatricial tissue, thus forming an extensive stricture from which double infection may occur. Again, this stricture may be the result of true tertiary inflammation or ulceration, the rectal wall being infiltrated with syphilitic neoplasms, or by becoming organized into constrictive tissue, producing a stricture. The true explanation of the preponderance of stricture in women, whether specific or otherwise, is to be sought for rather in the anatomic relations of the rectum than in any constitutional diathesis. The site of the stricture is generally at or about the attachment of the fibers of the levator ani. This possibly plays an important causative factor indirectly, there being more or less constriction here. consequently if there is any ulceration the power of resistance in the patient is not sufficient to overcome the trauma. Here it is that the feces meet the first resistance, and where these strictures undergo contraction, and chronic inflammation follows. While iodids are usually prescribed in these conditions, they are not of curative value, and it is only by incision and eternal mechanical dilatation that these strictures of specific nature can be made tolerable.

DISCUSSION.

DR. ARTHUR DEAN BEVAN, Chicago: Almost all cases of benign stricture of the rectum are due to gonorrheal inflammation, and not to syphilis. I have had the opportunity of following the development of stricture of the rectum from a gonorrheal inflammation in two instances of gonorrheal proctitis in females. The inflammation involved the urethra and vagina, later the rectum, and within a short time a distinct stricture of the rectum formed. Gonorrhea occurs in the female twenty times as often as it does in the male child, because the female child is peculiarly susceptible anatomically and because of the ease with which infection of the vagina occurs in the female, and the difficulties with which it can inoculate a small urethra in the male child.

DR. J. R. PENNINGTON, Chicago: I have had a number of cases of gonorrhea of the rectum, and while the gonococcus was demonstrated to be present, as yet I have not seen a closed stricture of the rectum following. There has been much thickening of the rectal walls in some of them, but not sufficient to dignify it by the name of a stricture of large caliber.

X-Ray Diagnosis of Stricture of the Esophagus.

DR. SIDNEY LANGE, Cincinnati: The fact that organic and spasmodic strictures may have points in common and may be combined, and the fact that in neurotics, in valvular heart disease, and in mediastinal tumor cases the passage of the stomach tubes and bougies is distinctly dangerous, establishes the value of the *x*-ray method. It consists in giving a small bismuth capsule, a large bismuth capsule, and then several swallows of bismuth mush. From a study of the act of deglutition itself any obstruction to the passage is at once evident; the size and extent of the obstruction, and whether organic or spasmodic can be determined. Weak or deficient peristalsis is registered by the stoppage of the bismuth capsule, and thus an early diagnosis is possible before the stomach tube meets with resistance and even before dysphagia is present. Increased mediastinal pressure can thus be recognized early by the stoppage of the bismuth capsule in the esophagus. There exists a sphincter at the entrance of the esophagus, as well as at the cardia. Instrumentation often serves to increase the spasm of these sphincters. The non-irritating bismuth mush will relax it.

Legal Responsibility.

DR. A. E. STERNE, Indianapolis: There should be more careful examination and observation of persons accused of criminal acts and for whom the plea of insanity is advanced. In my opinion, insanity once established is a clear basis for irresponsibility in a legal sense, but at the same time I emphasize the necessity for not permitting criminals who have been declared to be of unsound mind to be set at liberty. I deny the psychiatric entity of so-called moral insanity in the so-called temporary emotional state, and I would deny them altogether the protection of law and medicine. At the same time morbid tendencies and perversions associated with other evidences of mental unsoundness clearly establish insanity and are symptoms of well-defined psychoses. The existence of a mere delusion unaccompanied by other signs of mental impairment do not establish insanity; but, on the other hand, the existence of a delusion even of a single variety associated with definite signs of mental and physical defect is a sufficient basis for such a plea.

The Human Element in Medicine.

DR. P. ZENNER, Cincinnati, Ohio: As practitioners, we are too prone to overlook the human element in disease. We not only overlook the characteristics of the patient, his special physiologic or pathologic reactions, but we are apt to forget that great factor in health and disease, his mental attitudes and aptitudes. A powerful therapeutic agency is the mode of examination of the patient. The physician may harm his patient by neglect or delay in telling him the result of the examination of the urine, for instance, the idea arising in the patient's mind that he has serious disease, of which his physician is unwilling to speak. The human element figures materially in diagnosis and prognosis. The mental element frequently plays a large or controlling part in the case. Let each of us ask himself: What of present suffering is due to the mode of examination, the diagnosis or prognosis given, or the treatment instituted, and how much can be gained by remedying any harm thus done, or by well-directed suggestions, or by a heart to heart talk with the patient as to what his mind has done, and may do, in the way of mental and physical health?

Object Lessons in Otology for the General Practitioner.

DRS. J. A. STUCKY and S. B. MARKS, Lexington, Ky.: We have endeavored to impress the general practitioner with the necessity of a careful and routine examination of the ears of children in all febrile conditions, especially in the acute exanthemata. To accomplish this the medical schools of our country must offer a better course of instruction in the diseases of the throat and ear. We advise that a free myringotomy be done in cases of earache after pain has persisted for a few hours, with no relief from local and general measures, whether there be fluid in the middle ear or changes in the drum membrane, as it relieves the pain and renders further trouble much less likely. A search must then be made for the cause of the trouble. The value of microscopic examination of every aural discharge can not be over-estimated, since the various organisms causing middle-ear suppuration and consequent mastoiditis differ in virulence. The differential leucocyte count is also of value. Every patient with mastoid tenderness should be carefully watched; the disappearance of pain and restlessness means the same thing in mastoiditis as in appendicitis—a relief of local pressure, the pus escaping externally or internally. The so-called classical symptoms should not be waited for in mastoid disease, but early operation done, thereby conserving the patient, as less anesthesia is required, there is less shock, the middle ear is frequently saved, and complications are avoided. Chronic conditions of the middle ear should always be considered dangerous and should receive careful attention and operative treatment if necrosis be present. The treatment of the constitutional phase of every ear case, no matter how mild, is important in regard to the intestinal tract.

MEDICAL SOCIETY OF VIRGINIA.

Thirty-ninth Annual Meeting, held in Richmond, Oct. 20-23, 1908.

(Concluded from page 1724.)

Cesarean Section.

DR. LEWIS C. MORRIS, Birmingham, Ala.: In infected cases the incision is closed as usual by continuous through and through sutures of catgut into the uterine wall, except for a distance of three centimeters at the lower angle. A Mikulicz wick is introduced through the abdominal wall into the uterine cavity. It is important to minimize the loss of blood, and this is best accomplished by an assistant compressing the uterine artery, or by encircling the cervix with a soft rubber catheter before the uterine incision is made. In predetermined, elective Cesarean sections it is never necessary to remove the uterus except where there is uncontrollable hemorrhage from the placental site, or where there is carcinoma of the cervix or a myxomatous tumor which can not be enucleated. Where there is exhaustion and infection, or probable infection, the uterus should be removed or treated by drainage through the abdominal wall.

If it is desired to prevent future conception tie off the tubes at the outer ends. Where a diagnosis of positive indication for Cesarean section is made before the onset of labor, I am convinced it is safest and best to carefully compute the termination of gestation, and upon its arrival operate regardless of labor. I am also convinced that the diagnosis of the conditions necessitating Cesarean section can most frequently be made before the onset of labor. If this is done the operation becomes one of election and, in the hands of the expert and done under proper conditions, maternal and infantile mortality should be almost nothing or no greater than in clean, interval appendectomies.

DISCUSSION.

DR. E. MCGUIRE, Richmond: In a case of puerperal eclampsia with undilatable cervix I performed a vaginal Cesarean section which was attended with practically no loss of blood, and recovery was uneventful. The operation is one of the most important for cases of this kind, being quick, easy and safe. In a case in which the child had been dead for five days, and the woman septic, I did a Porro, but death ensued. In a

Porro operation performed on a woman whose uterus ruptured while she was on her way to the hospital, there was but little bleeding and no shock, and the patient was well in three weeks. I agree with Dr. Morris as to the safety of the Cesarean section, unless the child is dead. I do not, however, see the value of draining through the abdominal wall, because if there is infection, the germs have penetrated the tissues and are beyond the reach of the drain; and if flushing is necessary it is best done through the vagina. To sum up, in aseptic cases, Cesarean operation is best; but in the septic do the Porro.

Dr. G. T. Harrison, New York: I agree with Dr. Morris' conclusions, but do not think that the classic operation is indicated in cases of placenta prævia or undilatable os. In these, vaginal Cesarean section is superior to the Saenger. The transverse incision through the fundus is not so apt to be followed by hemorrhage.

Dr. J. W. Bovée, Washington: Sterilization should only be done when life will be endangered by future pregnancies. The method of sterilization by ligating the tubes is uncertain. One should be certain that there are no supernumerary tubes and that the ligatures do not cut through them. It is necessary, too, to cover the cut ends with peritoneum to insure closure. Drainage of the uterus is best done by taking advantage of pendency, and, therefore, through the vagina with a stiff tube of considerable caliber. As to vaginal Cesarean section in the puerperal woman near full term, the vaginal wall is prepared by Nature for the passage of the fetus, and therefore, it is well dilated; but the operation adds traumatism, and in the closure of the wounds in emergency work one is very apt to make indiscriminate approximation of the structures resulting in a relaxed perineum.

Dr. L. C. Morris, Birmingham, Ala.: There is practically no mortality rate in Cesarean sections performed in aseptic cases. There are certain patients who die in spite of any procedure, but these are rare, and in the majority of cases drainage through the abdominal wall is best. I agree with Dr. Bovée as to the necessity for covering the cut end of the tube, but in these cases rapidity is a desideratum, and section between ligatures is reasonably safe. As to hemorrhage, the method described is very quick and absolute.

Sacral Hematoma.

Dr. E. T. Brady, Abingdon, reported a case of spina bifida converted into a hematoma during breech presentation, the breech presenting. It was supposed to be the bag of waters and an attempt was made to rupture it, but, fortunately, unsuccessfully. The tumor weighed 9 ounces, the baby 4½ pounds. The former was removed three weeks after birth and the latter is living.

New Treatment in Hypertrophied Prostate.

Dr. J. W. Hunter, Norfolk, discussed the Roentgen ray treatment for this condition and reported an apparently hopeless case in a man aged 81 who had been greatly improved and symptomatically cured. He thinks that the full physiologic dosage should be given. The patient is placed in Sim's position, and the perienum irradiated. He believes that the new treatment will be followed by brilliant results, though he considers it better suited to cases of the first or second degree of prostatic hypertrophy. It is without mortality and, in careful hands, free of danger.

DISCUSSION.

Dr. A. L. Gray, Richmond: We can not hope for much in *x*-ray treatment of hypertrophied prostate, because the increase of connective tissue overbalances that of the cells. If the reverse were true, then the rays would be of benefit. We should not consider a post hoc cure as a propter hoc. While it appears that Dr. Hunter's claim of a cure is good, we should wait for others before deciding the case affirmatively.

Dr. S. G. Slaughter, Lynchburg: Surgery of the prostate is, as a whole, disappointing; manual massage is disappointing. The static wave has, in my hands, produced symptomatic cures.

Dr. J. W. Hunter, Norfolk: I do not claim to cure every case of hypertrophied prostate or even a small percentage of them; I only give the result in my case in which surgery was contraindicated and medicines proved unavailing. With the rays there was a symptomatic cure. As to surgery of the gland, while in some hands it is successful, it is curious that so many patients have died one or two months after operation. There has been no mortality from the rays.

Two Cases of Mechanical Obstruction of the Bowel.

Dr. J. Shelton Horsley, Richmond: In one case there was a band which crossed the ileum about six inches from its termination. An artificial anus was made and two weeks later it together with several inches of intestine on each side of it, was excised and union made with sutures. Recovery was complete. In the second case there was volvulus of the sigmoid which had caused gangrene of all the sigmoid, the upper part of the rectum and most of the descending colon. Operation was performed under cocain, and the gangrenous bowel being excised, the colon was brought down where it was healthy and sewed in the upper corner of the wound. There was not a sufficient amount of healthy rectum left to do an anastomosis. The patient made a satisfactory recovery and left the hospital at the end of four weeks.

Some Further Applications of the Fowler-Murphy Method.

Dr. Southgate Leigh, Norfolk: I wish to emphasize the good results obtained from elevation of the patient while on the right side instead of on the back after operation for appendicitis. This position is almost as important as the elevation, and I have yet to see a case in which it did not aid drainage. Elevation is as applicable in operative work above the pelvis as in others. In septic cases the position is to be aided by salt solution in the bowels and by other measures as indicated. It should be especially appreciated by the country physician when immediate operation for appendicitis is impossible, as because of it infection is kept from spreading. It should be maintained in the transportation of patients to hospitals.

The Economics of Appendicitis.

Dr. W. L. Peple, Richmond: Appendicitis is to be considered from the standpoint of the patient, and such methods of treatment undertaken as will tend to lessen the stay in bed and minimize the chances of hernia, fistula, obstruction, etc. Second only to the saving of life is the big economic question of cost in time and money to the patient. To drain the abdomen of a working man is usually to drain the resources of his entire family. By a proper choice of incision in certain cases, the stay in bed may be cut down by weeks, and a hernia requiring another operation averted. We can not settle the question of drainage by failing to drain cases that demand it. In a large majority of drainage cases we expect recovery; the lay issue of saving life is not paramount, and we should, in these cases, do as little damage to the abdominal wall as possible and leave its cut or separated parts in such relation to one another that a good functional result may be confidently looked for.

IDAHO STATE MEDICAL ASSOCIATION.

Sixteenth Annual Meeting, held at Boise, Oct. 8-9, 1908.

(Continued from page 1636.)

SYMPOSIUM ON ROCKY MOUNTAIN SPOTTED (TICK) FEVER.

Clinical Phases of Rocky Mountain Tick Fever.

DRS. J. L. STEWART and W. F. SMITH, of Boise, presented this paper, read by Dr. Smith. They stated in brief: Dr. E. E. Maxey, Boise, was the first to describe the symptoms of this disease. It usually begins with malaise, chilly sensations, occasionally a distinct chill, and general stiffness and soreness all over the body, especially in the back and legs. Occasionally there is headache and nosebleed. The tongue is coated with white fur, later becoming brown; it is dry, cracked in the middle, and has moist edges. Constipation is usually obstinate. The fever is of a continuous type, ranging from 100 to 104 or 105 F. The eruption appears in from three to five days, usually first on the back, ankles and wrists, spreading gradually to limbs and body, and to the palms of the hands and soles of the feet. Late in the disease the eruption may be seen in the mouth and throat. The rash at first consists of red maculæ, gradually becoming darker to brownish, then hemorrhagic, which appear in successive crops and coalesce and become blotchy, often forming large hemorrhagic areas. Delirium is frequent, the spleen is enlarged, bronchitis is frequent, with tendency to pneumonia in alcoholics, and in severe cases there is apt to be a semicomatose condition. Pulse is slow and full; urine is scant, high colored, occasionally hematuria, rarely albuminuria. Blood examination shows débris of broken down red blood corpuscles and iron pigment, slight leucocytosis; hemoglobin is reduced sometimes as much as 50 per cent. Complications noted are: Sloughing of scrotum, palate and pharyngeal mucous membrane, bronchitis, intense intoxication, cardiac dilatation, acute mania, and in later stages in aged patients there may be cyanosis. The period of incubation varies from five to seven days. The mortality is probably from 5 to 10 per cent.

Causal Factors, Mortality and Geographical Distribution in Idaho.

DR. E. E. MAXEY, Boise: From information received from ninety-five physicians of the state, from the state immigration commissioner, the state auditor's office, the state live stock commission, and other reliable sources, the following statistical information is compiled:

1. There are approximately 375 cases of spotted fever in Idaho yearly.
2. Ticks are reported found in every county except Latah. The ordinary wood tick seems to be the prevailing species.
3. Rabbits, gophers, coyotes, ground squirrels, badgers, and chipmunks are found in abundance over the entire spotted fever area.
4. Horses and cattle are found in large numbers in all counties.
5. Practically all sheep are fed, sheared, lambed, and grazed only in the fifteen lower counties.
6. At least 38 per cent., probably more, of cases occur among sheep herders or those handling sheep; 35 per cent. occur among those leading an outdoor life; 8 per cent. were miners or prospectors; 6 per cent. stockmen; 5 per cent. farmers.
7. All ages and both sexes are attacked, if exposed to infection.
8. History of tick bite has been found in 81.5 per cent. of the Idaho cases in which observation was made.
9. Seventy-one per cent. of the physicians who have treated spotted fever accept the tick-bite theory as method of infection; 29 per cent. had no theory or thought it due to *contaminated* water.
10. A majority of the cases occur in April and May.
11. The chief complications are meningeal irritation, pneumonia, nephritis, cardiac weakness, and gangrene of skin.
12. Death rate varies from 3.8 to 11.4 per cent.; the average mortality is 4.8 per cent.
13. The principal infected areas of the state are in Washington, Canyon, Ada, Elmore, Blaine, Lincoln, Cassia, Oneida, and Bannock counties; *less frequently* the disease is found in Boise, Owyhee, Twin Falls, Bear Lake, Bingham, Fremont, and Custer counties, very rarely in Kootenai county.

There is marked similarity in geographical distribution of spotted fever and the areas of the state occupied by the sheep industry; and in view of our present knowledge of relation of tick to this disease, this relation may be explained by one of two conditions: (a) Either the sheep, sheep-dog, horse, jack rabbit, gopher, ground squirrel, chipmunk, coyote, or badger, any or all of them, may be subject to spotted fever in Nature, the tick becoming inoculated by feeding on the sick animal, and then carrying the infection to man; or (b) great numbers of female ticks are infected by man during the spotted fever season and, through their progeny, carry the infection over to the following spring. In either case the sheep, dogs, and horses may act only as common carriers or distributors of the infected ticks.

Recent Investigations of Rocky Mountain Spotted (Tick) Fever in Montana and Idaho.

DR. H. T. RICKETTS, Chicago: Prior to April, 1908, my investigations demonstrated (1) that the character of the disease is a generalized invasion of the body by an as yet unrecognized and uncultivated micro-organism, as evidenced by the ability to reproduce the disease in guinea-pigs or monkeys by injecting patients' blood serum or by the bite of a tick, and by maintaining the disease in these animals by methods of passage, and also that the disease is exclusively an acute infection and recovery is followed by immunity; (2) that the disease is transmitted to man by the bite of a tick, the life history of the tick and its various relations to the disease were also definitely determined; (3) from the accurate knowledge thus obtained certain preventive measures have become manifest, that is, avoiding infected localities in the spring, individual precautions if compelled to visit infected areas, and measures to decrease the number of ticks, by oiling domestic animals and clearing off sage brush and timber and destruction of rodent animals. In the spring of 1908 I examined several Idaho cases and found that the clinical features of the Idaho disease were similar to those occurring in Montana, and I succeeded in inoculating guinea-pigs from these patients. At the same time guinea-pigs immune to the Montana disease were inoculated, with negative results, thus conclusively demonstrating the identity of the disease in the two states, the Idaho strain being apparently much milder. In May, 1908, I began experiments through which I have demonstrated that what seems to be the prevailing tick near Boise and Mountain Home, is capable of acquiring and transmitting spotted fever, and that the Idaho tick can acquire and transmit the Montana spotted fever. I also tentatively demonstrated that the Montana tick may acquire and transmit the Idaho disease.

In my Montana experiments this year I demonstrated that the gopher, ground hog, chipmunk, rock squirrel, and mountain rat are susceptible to spotted fever, and further that these animals may be sick with spotted fever and yet show no clinical features of the disease as does the guinea-pig. It is yet to be demonstrated what other animals are susceptible to the disease, and what animals, if any, actually suffer from the disease in Nature. The difference in virulence of the Idaho and Montana cases may be explained either through the difference in variety of tick or a difference in the animals which act as tick hosts in the two states. This and many other important features yet remain to be worked out.

Indications for State Control of Rocky Mountain Tick Fever.

DR. T. D. TUTTLE, Billings, Mont.: The disease first appeared in Montana in the spring of 1885, since when the number of cases has gradually increased, with a death rate of from 60 to 90 per cent. The disease probably appeared in Idaho before it did in Montana and infection very likely extended from Idaho to Montana. Tick fever is also found in Washington, Oregon, Wyoming and Utah. Dr. Emil Starz of Helena made the first scientific study in 1901 by examining the soil and water of the infected region, but with negative results. In 1902 Wilson and Chowning were employed by the Montana board of health to study the disease and their findings are well known. In 1903 Anderson was able to corroborate the findings of Wilson and Chowning. In 1904 Stiles made extensive studies, but was unable to confirm findings of Wilson and Chowning and Anderson, and in 1905 Francis' studies were entirely negative. In 1906 Drs. Ricketts and King took up the work. Both succeeded in inoculating guinea-pigs and in transmitting disease from guinea-pig to guinea-pig through the bite of a tick. Neither was able to find the hematozoa described by Wilson and Chowning. The life history of the tick was studied by Ricketts, and infected ticks were found in Nature. This work of further [illegible] shoul [illegible] by comp [illegible] men of national reputation, and at public expense of all states infected with the disease. To fight the disease we must eliminate the tick from inhabitable districts. This is probably best done by clearing off and settling the land for agricultural purposes, and in some localities by oiling all domestic animals.

Discussion on Symposium on Tick Fever.

Dr. J. R. Numbers, Weiser: Tick fever was first discussed by this association twelve years ago. I was firmly convinced that the tick was the principal factor in the inoculation of the disease. While Dr. Tuttle mentions the period of incubation in Montana as practically about seven days, it has been my observation in Idaho that the period of incubation is longer. Of course, most of the cases occur among people who are constantly exposed to tick bites. It is nothing unusual for some of them to have had on their person many ticks and many tick bites for weeks, and it is impossible in most of these cases to tell when the inoculation took place. But I have noticed that people who lived in town and would go out into the sage brush for a day and come home with one or two tick bites would often go for eleven or twelve days before showing evidence of disease. It is rare indeed for anyone living in town to have this disease unless they have made a recent visit to the foot-hills or sage brush plains. Twenty-one years ago Washington County was practically a cattle and horse country, for there were very few sheep in the valley. If sheep came into the county they came after the lambing and shearing periods and were driven right through up into the hills, and after a time of year when one was likely to get this fever. About three years after I went to Weiser, eighteen or nineteen years ago, the first case of spotted fever I ever heard of was reported in the Payette valley. I did not see any cases for two or three years more, but I heard of several cases over there each year, and it occurred to me that it was not a very serious disease or that they were very fortunate, as I had never heard of anyone dying at that time from it. My first patient came into the office just at the period when the eruption shows on the wrists and ankles and he had considerable fever, but his was not an aggravated case. After puzzling over it considerably and after I had told the man that I did not know what was the matter with him, it seeming to me to be more like an upside-down case of measles, an old man who happened to be in the office at the time and who had seen some of the other cases, said it was a case of spotted fever, and from that time on I knew spotted fever when I saw it. Now, about this time they were beginning to feed sheep and sheep were held around that locality in the spring until after lambing and shearing, and as soon as the sheep came we began to have spotted fever. Prior to that time, people had been going out into the sage brush and were bitten with ticks, but not until after the sheep were brought in did we have any spotted fever. The sheep herders and the people who were out in the sage brush were the first to get the disease.

For a few years after that there was spotted fever in the lower valley, but no cases in the upper valley. As those valleys were settled up and brought under cultivation, and sheep were driven up there during the lambing and shearing season, tick fever has been prevalent there; and, fortunately, there are fewer cases in the vicinity of Weiser. One or two things have occurred to me in regard to the severity of the disease. In the average person who has it, the sheep herders and young cattlemen, and young people in general, I have never noticed a fatal case, but in isolated cases, especially when old people are attacked, there is a heavy mortality. In these fatal cases the course of the disease is entirely different. The eruption shows up scarlet colored spots at first, followed by a dark mottling of the skin and a well-defined eruption, and very scanty urine. At first the patient is not very ill and the disease is usually allowed to run until by the time the physician sees the patient it is too late. There is absolute suppression of urine, a very small amount of high-colored urine being obtained by catheter; temperature is usually subnormal; and other conditions which result fatally in ten or twelve hours. In another class of fatal cases the disease attacks very stout people, and those who have a history of rheumatism. In the younger people of this class the temperature runs very high, the eruption coming out usually bright scarlet and becoming thicker and thicker until there is not the size of a pinhead that is not covered; after the fifth or sixth day delirium develops, apparently a profound toxemia and suppression of urine; and the disease is apt to prove fatal within two or three days.

Dr. L. P. McCalla, Boise: Dr. Ricketts' work has proved conclusively that the tick is the great if not the only factor in the case, though a great deal remains to be done along that line. This brings up the question of how we are to get rid of the tick. What can we as physicians do, and what can or should we ask the coming session of the legislature to do in the way of helping to study and eradicate this disease? Of course, the disease is not so fatal in this community as it is in Montana, but if we can get help from the legislature I think we could carry this work on.

Dr. J. M. Taylor, Boise: Dr. Maxey spoke of the disease being confined to the Snake River plains and to the Bear River valley, and I wonder if the Bear River valley in Utah is also an infected area. I have heard it suggested that the rabbit bears a probable relation to this disease, because it was a well-known fact that rabbits frequently disappear from certain localities for one, two or three years on account of some epidemic among them.

Dr. E. W. Kleinman, Hailey: I have seen three cases of spotted fever since returning from the recent session of the American Medical Association. The first occurred July 31 on the Malad River, the second on August 15 up the canyon near Hailey, and the third case on September 10. The first two patients got along nicely and the third one is still under treatment. Five years ago when I first came to this country, I was led to believe that this disease was to be seen only during the early spring months. A boy from Shoshone, where I was then located, was taken ill, and notwithstanding the fact that the people stated it was spotted fever and the attending doctor had so diagnosed the case, I had never heard of a case later than June, and I took occasion to criticize the diagnosis, but later developments have proved that the doctor was wiser than I.

Dr. E. E. Maxey, Boise: Infected areas extend down the Bear River valley into northern Utah, and the disease is rather commonly found in parts of eastern Oregon in the sage brush country. In the upper Snake River valley, the only cases reported from Fremont County were reported by Dr. Hargis of Ashton, near the eastern part of the county. He reports seeing an average of two cases annually, one-third of his patients gave history of tick bite and all died. Of course, there is a question as to diagnosis here, but I think Dr. Hargis' cases were probably of the Montana malignant type. Dr. Price of Rigby, near the southern boundary of Fremont County, reports having seen two cases within the last four years. Fifty per cent. of his patients gave history of tick bite and none died. Dr. C. Wardell Stiles, Washington, D. C., states in a communication that he recently had occasion to study a large number of ticks from the Bitter Root valley and to compare them with specimens from California. Up to this more recent study he had not been able to determine clearly between the Montana and California species, but with his present material it seems clear that the Montana tick of the Bitter Root valley, namely, *Dermacentor andersoni*, is entirely distinct from the California tick known as *Dermacentor occidentalis*. Dr. Stiles states further that he has examined few ticks from Idaho and is not prepared to commit himself to a definite statement, but that so far as his examinations have gone he believes the Idaho species to be distinct from the *Dermacentor occidentalis* of California, and to be closely allied to and possibly identical with the Montana tick *Dermacentor andersoni*.

Dr. H. T. Ricketts: I meant to state in speaking of the virus in the salivary glands that the presence of the micro-organisms were demonstrated by means of inoculation experiments. We have never been able to see the micro-organisms. Concerning the species of ticks, not long ago some time during the summer, I sent specimens to Dr. Stiles and Dr. Banks of Washington. Dr. Stiles replied that he thought the Idaho tick was different from the Montana tick, but would want to have more material before he could come to a definite conclusion about it. He stated again that the Montana tick is the *Dermacentor andersoni*. Dr. Banks responded, saying that the Idaho tick was certainly different from the Montana tick, so far as he could see an entirely different species. Dr. Banks recently published a new index of the ticks of the United States, in so far as they are known, and he differentiates between the Montana tick and the Idaho tick. Concerning the question of spotted fever in August, the disease does not occur in Montana after July usually, rarely in August and sometimes as late as October. The season for the adult ticks is in the spring. They are rarely found in Montana after July 1 and until February, but I have found them in Montana in September, but not many of them. The development of the tick depends on temperature and moisture; some develop more rapidly and some more slowly. In Idaho Dr. Maxey and I went out last spring during the spotted-fever season and we found some young nymphs on some of the gophers and adult male and female ticks on horses. It is certain, therefore, that some of these ticks would develop as adult ticks later in the summer. I was going to say something about the serum used in the treatment of these cases. It was taken from a horse. The infection of the horse was proved and the horse recovered, it being then bled to death in order to get as much serum as possible. The serum was given in small quantities and in large quantities, and in one case intravenous injection was resorted to. The number of cases treated in this way was too small to draw any definite conclusions. Usually the cases went through as though no serum had been given. We have no means of determining at present whether this is an antitoxin serum or not. We can not cultivate the organism, but if the serum happens to be an antitoxin serum it will probably be of great value in the treatment of spotted fever.

Dr. W. F. Smith, Boise: Dr. Maxey said that in some of the replies received by him some of the physicians adhered to the opinion that the disease was due to contaminated water. I was of that opinion until one or two things changed my mind. One patient went out to his sheep camp and I cautioned him about drinking the water out there, so he took a case of Idanha water along and drank nothing else, except of course in cooking and in tea and coffee. He had been out a great many times prior to this time, and on the other trips he had been drinking the camp water, but this time, though he drank none of the camp water, he contracted the disease. I told him if he had not drank the Idanha water he might have been all right. I also had the water examined on two occasions by a chemist in Salt Lake, and it was found to be absolutely pure and nothing was found in the water that could produce any trouble watever. The water examined was taken from the spring used by this camp. These things proved to me that the water supply had nothing to do with the disease. Another interesting case that I recall was that of a child who had not been out of town, but she had a pet lamb, and about a week after the lamb was taken to the house the child was taken down with spotted fever. The tick was found on the child and it must have been on the lamb. While most cases have occurred in April and May I have had cases in the latter part of August, several in February, and one case I went to in three feet of snow in a mountain town. I have never seen nephritis in any of the cases I have had.

Dr. T. D. Tuttle, Billings, Mont.: In regard to the sheep question, there seems to be something crooked in the condition. Either the tick is different in Montana and Idaho or the sheep are different. There are over 5,000,000 sheep in Montana, but they are all on the east side of the state, and on the west side, where we have spotted fever, sheep are rare. There is no spotted fever in the sheep district. It may be a tick here that lives on the sheep that transmits the disease. The special species of tick that live in Montana do not attach themselves to the sheep. If they did it would make the fight against the tick much harder. At present the experiment of oiling cattle would be comparatively easy to carry out. The question of getting anything from the legislature in the state should be gone into. Resolutions are good things, but they have not so much weight as a physician going to a legislator and saying what he thinks ought to be done. The family physician has great influence.

Ocular Manifestations of Some General Diseases.

Dr. R. L. Nourse, Boise: The eye, directly or indirectly, reflects or participates in a large number and variety of general or systemic diseases, particularly cerebral, cerebrospinal and constitutional affections. Among these are: The ocular manifestations of syphilis, both hereditary and acquired, through its effect on the brain and cord and the eye structures themselves; and the optic neuritis, papillitis and choked disc caused by cerebral hemorrhage, gummata, meningitis, brain abscess, hydrocephalus and brain tumors. Optic neuritis frequently follows infective diseases, and toxic amblyopias may be due to use of tobacco and alcohol. Heart and blood diseases, such as endocarditis, endarteritis and aneurism, may cause disastrous eye lesions from embolism and thrombosis. Pernicious anemia gives a characteristic eye ground. Rheumatism ranks next to syphilis in its responsibility for eye diseases, affecting nearly all structures of the eyeball. Arteriosclerosis, pyemia, gonorrhea, tuberculosis, scrofula and eczema are likewise prone to exhibit their baneful effects on the eye structures. Exophthalmic goiter and hysteria are noted for their eye symptoms, and the effects on the eye structures of diabetes and diseases of the kidneys are important.

INTERNATIONAL CONGRESS ON TUBERCULOSIS.

Held at Washington, D. C., Sept. 28 to Oct. 3, 1908.

(Continued from page 1726.)

SECTION VI.—STATE AND MUNICIPAL CONTROL OF TUBERCULOSIS.

President, Surgeon-General Walter Wyman, Washington, D. C.; secretary, Dr. J. W. Kerr, Washington, D. C.

A Federal Bureau of Health.

Prof. Irving Fisher, Yale University, president of the Committee of One Hundred on National Health:

The Committee of One Hundred on National Health was organized in the Spring of 1907. Its aim is to secure a bureau or bureaus of health under the Federal Government, as it is believed that in this way tuberculosis and other diseases can be most successfully reduced. The committee has received the cordial support of President Roosevelt, the late ex-president Cleveland, Mr. Taft, Mr. Bryan, the governors of various states and senators and congressmen. Last summer the health plank of the Committee of One Hundred was adopted in the platforms of the Republicans, Democrats and Independence League. The Republican platform reads:

> We commend the efforts designed to secure greater efficiency in national public health agencies and favor such legislation as will effect this purpose.

The Democratic platform reads:

> We advocate the organization of all existing national public health agencies into a national bureau of public health, with such power over sanitary conditions connected with factories, mines, tenements, child labor, and such other subjects as are properly within the jurisdiction of the Federal Government and do not interfere with the power of the states controlling public health agencies.

The movement has the endorsement of the American Medical Association and other medical organizations, the American Public Health Association and other hygienic organizations, the United Mine Workers of America and other labor organizations. It is closely linked with the movement toward the preservation of our natural resources. In the peroration of President Roosevelt's famous speech before the conference on the Conservation of Natural Resources, he said:

> Finally let us remember that the conservation of our natural resources, though the gravest problem of to-day, is yet but part of another and greater problem to which this nation is not yet awake, but to which it will awake in time, and with which it must hereafter grapple if it is to live—the problem of national efficiency.

There already exists at Washington a Public Health and Marine-Hospital Service, but its work is chiefly confined to quarantine, to the care of sick sailors and to the examination of antitoxin at its hygienic laboratory. There is also the Bureau of Pure Foods, presided over by Dr. Wiley, and in the Census Office there is a Division on Vital Statistics. A proposition which has found favor with many in Congress is to utilize the Department of the Interior by transferring from it most of the bureaus not connected with health or education and to transfer to it the various scattered health agencies now in other departments. To the nucleus thus formed it is hoped to add a bureau of medical investigation and a children's bureau.

There is much difference of opinion as to the extent to which the Federal Government may constitutionally exercise health powers, but the committee is taking pains to avoid any controversy on this point by confining its recommendations to research and publication, entering into the field of regulation only so far as it affects interstate relations or the District of Columbia. It is hoped that the national capital may become a model city in sanitation as well as in other respects, in accordance with President Roosevelt's well-known plans. By holding up high standards in public and personal hygiene, the national government will aid in the national efficiency, not only directly, but by giving greater prestige and in stimulating to redoubled activity the work now being done by state and municipal boards of health. Public opinion holds sway in matters of health as elsewhere. It is largely for the purpose of impressing public opinion that these international congresses on tuberculosis are held. It is believed that a Federal organization of health, by persistently upholding health ideals and by the demonstration of methods of attaining and maintaining health, will keep the public interest from flagging.

First and foremost among the specific problems to be treated by this national organization is the problem of tuberculosis. At present circulars and pamphlets of information are issued by many state boards of health which might with greater advantage be issued by one authoritative central bureau and utilized by all. The circulation of such pamphlets, if issued by the Federal Government, would be far wider, the cost of distribution far less, and the authority and ability of those who write them would be much greater. Already the Bureau of Animal Industry in the Department of Agriculture has made important contributions to tuberculosis, not only by inspection of meats, but still more by the investigation of tuberculosis in dairy products, particularly butter. Several bills are now before Congress relative to tuberculosis and one was passed at the last session making compulsory the notification of cases of tuberculosis in the District of Columbia. The expansion of such work through a powerful national organization of health would not only give a great impetus to the crusade against tuberculosis but would utilize this crusade to bring about an improvement to American health generally.

Relation of the Proposed National Department of Public Health to Solution of the Tuberculosis Problem in the United States.

DR. CHARLES A. L. REED, Cincinnati: Tuberculosis alone causes the death of 140,000 persons and constant illness of two-thirds of a million more each year in the United States. The disease is preventable. The United States to-day has no national public health agency vested with power competent to cope with the evil. Both great political parties have committed themselves to the creation of such a national public health agency. President Roosevelt has signified his intention to bring to the attention of the Congress, at its session in December, specific proposals looking toward the correction of this unfortunate defect in our governmental organization. The object of my remarks is not to impress this Congress of scientists, for that is unnecessary, but I desire through this body to impress the people of the country with the extreme importance of supporting these proposals, to the end that lives may be saved and that science shall be given due honor in the practical government of men. The fundamental basis of prosperity is the productive energy of the people. It is the human factor, first, last and all the time that counts, but one that is taken all too little into account by publicists when they assume to talk learnedly on the great problems of national economics. I am confident that the chief national legislation of the immediate future will be based on the fact that a man's energy is his best asset, and that its full value depends on his health and his length of years. This movement is fostered, not only by human and economic considerations, but by the fact that the existing public health agencies established from time to time by our national government are insufficient and incoordinate and, to that extent and in consequence of that fact, are both unnecessarily expensive and disastrously inefficient in coping with this devastating evil.

In addition, they are scattered through the various departments of the government, and in consequence of this arrangement, or lack of arrangement, the Secretary of the Treasury is now the chief health official of the United States. The secretary of the Department of Commerce and Labor is in charge of the fundamental basis of a health department—the Bureau of Vital Statistics. The Secretary of Agriculture has the enforcement of the Food and Drugs Act, and also has charge of the Bureau of Animal Industry. The Secretary of the Interior is the sanitary administrator of the territories, of the Indian tribes and of the great national eleemosynary institutions. The Secretary of War has charge of the sanitation of our insular possessions, including the Isthmian Canal Zone. The Secretary of the Navy and the Secretary of War, under the advice and direction of their respective surgeons general, are, of course, in control, as they ought to be, of the health of, respectively, the navy and the army. Many other instances might be given to illustrate the fact that our national public health agencies, considered in the aggregate, are in no possible sense connected with a co-ordinating center or under the direction of an intelligent and purposeful centralized administration.

In considering the formation of a national department of health in relation to the control of tuberculosis, one of the first considerations is the limitation, under our form of government, of the state and national governments respectively. The laws in the various states are entirely inadequate and their complete lack of uniformity renders it impossible for the states to cooperate. And like laws by the states will probably not be enacted to any great extent until, under the initiative of the national government, the states shall send delegates to a representative body, a sort of council of states, which shall meet, as a legislature or the congress meets, in a session or sessions long enough to accomplish satisfactory results, and whose object shall be to formulate bills on various subjects and send them back to the legislatures for enactment. In this way alone can the states move with anything like satisfactory rapidity in meeting the crying demand, for like laws, for like conditions, not only as relates to great sanitary problems, including the problem of tuberculosis, but relative to many other problems that concern the economic and social welfare of the people.

Finally, we should attempt, through a council of states, to secure uniform state laws touching this and other important questions. We should have a strong federal public-health agency with which to do the national side of the work. The existing national public health agency could be assembled by transfer from the various departments in which they are now located into some one of the existing departments, and there organized under authority of additional law on the basis of highest efficiency. These agencies should be assembled in some existing department rather than organized into a separate and distinct department with representation in the cabinet. The fundamental importance of this health movement, as shown by this great congress, and by hundreds of other congresses and associations, demands that, for its fullest efficiency, it should be accorded the educational and moral force to be derived only from its titular recognition in the departmental scheme of our government. The two propositions fortunately are readily reconciled. This can be done by changing the name of the deparment in which the health agencies are assembled, thus avoiding the multiplication of cabinet officers. Thus, if it shall be found wise to make the Bureau of Vital Statistics the nucleus for the aggregated service, the name of the department in which it is located could be changed to that of "Commerce, Labor and Public Health." Or if it shall be deemed expedient to select the Department of the Interior the name of that department should be changed to that of Education and Public Health, which unlike the present title would mean and stand for something distinctive among our great national interests.

But I insist in the name of the medical profession, in the name of science, in the name of humanity, that a great governmental agency to conserve, as this one proposes to conserve, more lives, more homes, more property, and more money, than any other single agency in the whole plan of government, shall be accorded a status befitting its dignity and its worth to all the people.

SECTION II—CLINICAL STUDY AND THERAPY OF TUBERCULOSIS.

Rest and Exercise in Treatment of Tuberculosis.

DR. F. M. POTTENGER, Monrovia, Cal.: The functions of the body are best carried on when both rest and exercise in suitable proportions can be prescribed. The amount of each must be determined by the natural resisting power of the patient and the pathologic condition present. In prescribing rest and exercise the conditions of the respiratory, circulatory, digestive and muscular systems must all be considered, and special attention must be directed to the condition of the heart, and the ability of the patient to exercise without causing fatigue, increase of cough, shortness of breath, or rise of temperature. Exercise causes toxins to be thrown out into the blood stream, thus producing autointoxications which cause practically the same symptoms as injections of tuberculin; but owing to the fact that the dosage can not be controlled, and that the patient receives said dosage at a time when he is tired and not able to respond to his fullest capacity to the production of antibodies, the autoinoculation can not be considered a scientific method of administering bacterial vaccines. If work is to take the place of carefully prescribed exercise in the treatment of charity patients, it must be prescribed according to the needs of the individual, and the patient must not be permitted either to do hard work or to do more work than is consistent with his powers of endurance.

Ultimate Results of Sanatorium Treatment.

DR LAWRASON BROWN, Saranac Lake, New York: Of the first 300 patients at the Adirondack Cottage Sanitarium, 36 per cent. are untraced and only 10 per cent. of the last 2,400. Of the 1,209 patients now known to be living out of 2,553, 1,058, or 41 per cent. of the whole, are engaged in, or able to do, some work. Of these patients, 353 remain untraced, and if we consider only the 2,200 traced, 48 per cent. are able to work. Out of the 1,209 patients living, 87.5 are still able to work. Sixty-three patients who were discharged from fifteen to twenty-three years ago are still living. When it is considered that fifty years ago no one was ever thought to recover from pulmonary tuberculosis, results such as these are very encouraging.

Day Camp for Consumptives.

DR. DAVID TOWNSEND, Boston: Until recent years there has been little or no provision, in this country, for the type of tuberculous patient who, for one reason or another, is unsuitable for the incipient hospital or sanatorium, and yet is not sufficiently advanced to require treatment in an advanced hospital or home. Germany early recognized the necessity of some such place, and in 1900, largely through the efforts of Drs. Becher and Lennhoff of Berlin, the Red Cross Society opened a day camp for men at Jungfernhaide, near Berlin. In the summer of 1905, the Boston Association for the Relief and Control of Tuberculosis opened in Boston a similar camp, the pioneer one of its kind in this country. Another camp was operated in the summer of 1906, and in 1907 the camp was continued for eight months, closing Feb. 1, 1908. The equipment of these camps consisted of shacks and tents, for kitchen, administration, dining room and various other purposes. There were two nurses and a resident physician in attendance, a cook, two caretakers and several maids. The patients came for the day only, and were given two lunches and a dinner each day. The chief aim of the camp was educational, and much emphasis was laid on this side of the work. Each patient was taught the care of himself and how to prevent infection to others. A careful study of each patient was made and every effort exerted to relieve him from all worry and anxiety. Each patient was encouraged to confide in the matron and medical staff, and nothing was too trivial to receive attention.

Experience has taught that the day camp, when properly conducted, is of value, (1) on educational lines; (2) as it removes, for a time, the sources of infection from the home and the community; (3) as it enables cases which, although suitable for some reason or other can not go to a sanatorium to obtain proper care; (4) as it helps to complete the cure in some patients who have been discharged from a sanatorium. In addition, it has proven that a patient with tuberculosis is not hopeless until he dies. In many cases in the past the disease progressed and the patient died for no other reason than the lack of proper facilities for care. The *per capita* daily cost for an average daily attendance of 64, in 1907, was 51 cents.

(To be continued.)

Medicolegal

Observations of Physician While Collecting Are Not Privileged.

The Supreme Court of Missouri, Division No. 1, says that in the personal injury case of Chlanda vs. St. Louis Transit Co., where the whole trend of the plaintiff's case was to the effect that she could not walk without artificial aid, a physician was not permitted to testify that on a certain date, when he called at her residence relative to a bill for services in her behalf, he saw her walking without the use of crutches, and saw her go up a flight of stairs without their use. This was error.

Conceding that the witness was the plaintiff's physician at the time in question, yet the court thinks the offered evidence was competent. The statutory interdiction on the testimony of a physician or surgeon is salutary, but must be kept well within the banks of the prescribed statutory channel. He is incompetent to testify "concerning any information which he may have acquired from any patient while attending him in a professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or do any act for him as a surgeon."

The offered testimony did not come within the letter or the spirit of the statute. The physician was making no professional call on the plaintiff. He was not seeking information to enable him to prescribe for her or do any act for her as a surgeon. Admitting that facts gathered for that purpose while acting in a professional capacity are a sealed book, yet in this instance he was neither acting in a professional capacity nor was the fact inquired about in any wise necessary to treat his patient. In the law, as to that fact, the physician was the same as any other bill collector possessed with eyes. According to the common sense of the thing the matter was plainly without the province of a physician, and he was therefore competent to testify.

Things Not Provable in Action for Professional Services.

The Supreme Court of Arkansas says, on the appeal of Henderson & Campbell vs. Hall & Hughes, that the latter parties, two physicians, sued the former, a firm of lawyers, alleging that said firm engaged the professional services of the plaintiffs to visit, examine and report on the physical condition of a woman client of theirs who was alleged to have been injured through the negligence of a railroad company, and that the plaintiffs performed such services, and for the same the defendants agreed that they would pay to them the sum of $200. The answer admitted the employment for the purposes stated, but denied that the defendants had agreed to pay the sum of $200, or any other certain sum, but alleged that they had agreed to pay the sum that the services would reasonably be worth. They alleged that the services were worth $34, but they tendered $40.

Under these circumstances it was permissible for either party to introduce evidence as to the value of the services. But it was error to admit testimony that the plaintiffs brought about a compromise for the defendants with the railroad company, and that their services were worth $200 to the defendants because they made their case for them and got a compromise for them, that being without the issues, and highly prejudicial. The suit was for recovery of the value of medical services, and not for services as negotiators of a compromise.

Likewise it was error to admit the testimony of several physicians to the effect that the plaintiffs' services were worth $200 because they were not ordinary services, and the further fact that the plaintiffs might have had to attend court as witnesses. As the case of the client was settled before this controversy arose, it was pure speculation as to what the physicians might have been called on to do had not the case been settled. They were called to render professional services in a physical examination of a woman, and were entitled to pay for the value of those services, and not for any speculative incidents that might or might not have followed from this service.

Power of Conductors to Employ Surgeons in Emergency Cases.

The Supreme Court of Arkansas says, in the case of Bonnette vs. St. Louis, Iron Mountain and Southern Railway Co., an action brought by a surgeon, that it was alleged a stranger had been run over at night, and seriously or fatally injured at a station many miles distant from the principal offices of the company and from the residences of its principal officers, and that the conductor in charge of the train, and as agent of the company, employed the plaintiff, a resident surgeon, to render professional services to the injured man, and that it was necessary to amputate both thighs, which was done, with assistance, acting at the request and under the employment of said conductor. The company demurred to the complaint on the ground that it failed to state facts sufficient to constitute a cause of action against the company as it did not state that the conductor had any authority to contract for the services in question and failed to state any facts that would bind the company for the contract of the conductor in employing the plaintiff. The demurrer was sustained in the lower court, but the Supreme Court holds that that was error.

The Supreme Court quotes from several cases, as it says, to show that the authorities whether in the case of a stranger and trespasser or of an employé and passenger hold the company liable for failing to exercise ordinary care to administer to the absolute needs of the ones whose unfortunate injury it has produced, notwithstanding it may have been without fault in producing such injury, and notwithstanding the injury may have been the direct result of the party's own negligence. In so holding the company liable in such an emergency, it will be observed that the rationale of the doctrine, whether in the case of a stranger and trespasser, or of an employé or passenger, is found in the duty imposed by the dictates of common humanity. The authorities stress the moral obligation and find from that the legal duty to alleviate as far as possible the suffering and to administer to the necessities which the company has contributed, however innocently, to produce.

This court confesses, if the duty and the consequent liability for failure to discharge that duty grow out of the obligations which the impulses of our common humanity would suggest and impose, under such circumstances, then the court does not see that the status or relationship of the injured to the party producing the injury could affect the question of the plaintiff's right to recover; for, from the humane viewpoint, clearly it could make no difference whether the helpless and unfortunate victim of the accident were trespasser, employé or passenger. But the court merely cites the cases referred to in order to show the extent to which the authorities have gone.

It was here a question of the authority of the conductor to act for his company. The emergency created that authority. Some one must have authority to represent the company under such circumstances. The conductor was the highest agent on the ground, and was in command of the train that did the injury. Before sufficient time had intervened to ascertain whether the accident was caused by the negligence of the company, he certainly had at least the implied authority to protect his company by doing what might be necessary to lessen the damages in the event it should be afterwards ascertained that the company was liable. This authority would be sufficient to bind the company for his contract with the surgeon, but not for the surgeon's contract with others.

Constitutionality of Law Providing for the Detention and Treatment of Habitual Drunkards as Persons of Unsound Mind.

The Supreme Court of Minnesota says, in the case of Leavitt vs. City of Morris, that there is a clear distinction between a person who gets drunk and an insane person, and that it may be conceded that one who is simply a drunkard, but is able properly to take care of himself, his family, and his property, and is not a menace to the public, cannot be committed to and detained in a hospital for inebriates without his consent, for the personal rights and liberties of such a person are guaranteed by the constitution.

But the state, in the exercise of its police power, has the undoubted right to punish drunkenness, and to provide for the detention and treatment in hospitals controlled by it of those who are habitual drunkards, and have so far lost the power of self control that they are either incapable of properly caring for themselves or are a menace to the public weal. The state has the power to reclaim submerged lands, which are a menace to the public health, and make them fruitful. Has it not, also, the power to reclaim submerged men, overthrown by strong drink, and help them to regain self-control?

The state for many years has punished drunkenness as a crime by a fine or imprisonment. The trend, however, of legislation is to treat habitual drunkenness as a disease of mind and body, analogous to insanity, and to put in motion the power of the state, as the guardian of all of its citizens, to save the inebriate, his family, and society from the dire consequences of his pernicious habit.

Chapter 288 of the Minnesota laws of 1907, entitled, "An act creating and establishing a hospital farm for inebriates," etc., is of such a character. It is not a penal, but a paternal, statute, seeking, not the punishment of the inebriate, but the safeguarding of his interests and the safety of the public, by treating him as, what he is in fact, a man of unsound mind, and placing him under the guardianship of the state, to the end that he may be healed of his infirmity.

This statute is limited to habitual drunkards—that is, to persons who have lost the power or will to control their appetite for intoxicating liquors or narcotics, and have the fixed habit of drunkenness, who are in need of care and treatment, and to those it would be dangerous to leave at large. The difference between such persons and insane persons is one of degree only, and they lawfully may be so treated by the state without any impairment of their constitutional rights. The term "inebriate," as used in this statute, "includes every species of chronic inebriety"; that is, habitual drunkenness. Hence an inebriate, as defined by the act, is an habitual drunkard.

Wherefore, the court holds that the general scheme provided by this statute for the commitment to and detention at a hospital farm, maintained and controlled by the state, of the class of inebriates designated in the act, is constitutional.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal.

November 5.

1 *Introduction of Surgical Anesthesia. W. H. Welch, Baltimore.
2 *Surgery of the Prostate. S. Alexander, New York.
3 *Total Extirpation of the Lower Pharynx for Epithelioma, with Permanent Esophagostoma: Surgical Treatment of Cancer. M. H. Richardson, Boston.
4 *Bursitis Subacromialis, or Periarthritis of the Shoulder Joint. (Subdeltoid Bursitis.) (Continued.) E. A. Codman, Boston.
5 Serum Treatment of Epidemic Cerebrospinal Meningitis, with Report of Twenty-two Cases. (Concluded.) F. T. Fulton, Providence, R. I.

1. **Surgical Anesthesia.**—Welch discusses the introduction of surgical anesthesia from a historical and philosophic viewpoint, and emphasizes its benefit to mankind.

2. **Surgery of the Prostate.**—Alexander cites his previous views and practice, as published in the *Annals of Surgery*, in 1905. He gives the reasons which, by the end of that year, led him to conclude either that the technic was deficient and drainage insufficient, or that his views in regard to the pathologic anatomy of prostatic suppurations were imperfect. These considerations led him to treat prostatic abscess by prostatectomy through a median perineal incision, enucleating the lateral lobes through the wall of the prostatic urethra. He analyzes the results of treatment in gonorrheal prostatic abscesses from 1905 to February, 1908, either by perineal section and drainage, or by prostatectomy. He discusses the symptomatology and describes in detail his present operation. In no case has he found any complaint in regard to the character of the erection or the ability to have sexual intercourse. The sensation is not impaired, but the discharge of seminal fluid at the time of the orgasm is entirely absent. He has not altogether abandoned perineal section and drainage, but considers prostatectomy better practice in most cases.

3. **Cancer.**—Richardson holds that we must confine new methods—trypsin, *x*-ray, toxins, etc.—to inoperable cases, for he has seen many operable and favorable cases drift under them to inoperability and death.

4. **Bursitis Subacromialis.**—In this issue Codman continues the discussion of this subject in respect of prognosis and treatment.

Medical Record, New York.

November 7.

6 *Development of the Legal Relations Concerning the Insane, with Suggestions for Reform. A. M Hamilton, New York.
7 *Operative and Non-operative Fibroid Tumors of the Uterus. F. D. Reese, Cortland, N. Y.
8 *Bituminous Coal Smoke: Its Chemistry and Effects on the Health of Man and Plants, Works of Art and Commerce. J. W. Wainwright, New York.
9 Chronic Purulent Otitis Media. A. Wiener, New York.
10 Fracture and Dislocation of the Neck at the Sixth Cervical Vertebra in a Man of 60. Recovery. G. H. Williams, Fishkill-on-Hudson, N. Y.
11 Important Flatfoot Facts: for Assimilation and Dissemination. E. A. Tracy, Boston.

6. **Legal Relations of the Insane.**—Hamilton makes the following recommendations:

1. There should be obligatory information of the commissioner in lunacy in regard to the existence of all cases of insanity.
2. Though the commissioner in lunacy may have power to license private institutions, he should also be empowered to formulate additional requirements which would put some of them on a much higher standard than they occupy at present.
3. Commitments are chiefly to be looked on as reinforcements by the judge of the persuasions exerted by the friends, physician and family of the patient, and should be resorted to only when the latter can not be persuaded to go to the asylum.
4. Everything should be done to make the appeals of committed patients available. There should be severe punishment for the suppression of letters, or interference in any way with the alleged lunatic's rights.
5. There should be material refor[illegible] f the law regarding capacity and criminal [illegible] acts in themselves, in any relation they ma[illegible] re weight than heretofore.
6. There should be a departure from conventions in old and arbitrary definitions.
7. Special insane acts should be studied with reference to the crime itself in a way they have not been studied up to this time.
8. The attitude of the courts should be much more charitable to the medical witness than it is to-day, the intelligent medical man being put in possession of all the facts in the case and not being obliged to answer restricted questions which place him in a false position, and which are deficient in the presentation of the facts.
9. In all matters involving the determination of capacity or responsibility the medical man should be required to prepare a brief which should form the basis of his cross examination, and this, if necessary, must be supported by extraneous evidence, which has received the sanction of the court as to heredity, previous history, and facts communicated by others.

7. **Non-Operative Fibroids.**—Reese concludes that dysmenorrhea always calls for a thorough examination of the pelvic organs in uterine fibroid. Surgical treatment should be instituted only on a clear diagnosis and a positive indication. Mixed tumors of the uterus should be removed as soon as diagnosed. Simple fibrous tumors, save in exceptional cases, are amenable to constitutional and local treatment, and so do not demand operation.

8. **Bituminous Coal Smoke.**—Wainwright insists that bituminous coal smoke materially interferes with the welfare of the community: 1, By leading to fog and rain; 2, by shutting out sunlight and depriving us of certain qualities of light, of great importance in regard to changes in organic matter; 3, by depositing soot. He urges its suppression because a smoky atmosphere, by its exclusion of light, its content of suspended acid and irritating particles, is harmful to the tissues of the nose, throat, eyes, and especially the lungs and air passages, whether in a healthy or other condition; aggravates the discomfort of those suffering from all forms of heart disease; increases the distress of those who have nervous complaints; lowers the tone of the general health; is a peril to the aged; and diminishes buoyancy of spirit, as well as reduces still further an already lowered resistance to disease.

12 *Reflex Neuroses Arising from Ocular and Nasal Abnormities. S. L. Zeigler, Philadelphia.
13 The Mechanico-biologic Standpoint in Medical Problems. J. Wright, New York.
14 Purposes and Objects of Morbidity Statistics and the Methods of Collecting Them. J. M. Eager, U. S. Public Health and Marine-Hospital Service.
15 *The School Child. J. W. Van Derslice, Oak Park, Ill.
16 Ancient Greek Medicine. C. W. Super, Athens, Ohio.
17 *Obstetrical Paralysis. K. Osterhaus, Norfolk, Va.
18 Cause of Premature Separation of the Placenta. S. Robbinovitz, Brooklyn, N. Y.

12. **Reflex Neuroses.**—Ziegler discusses the influence of the eye on reflex neuroses, the nasal origin and individual manifestations of reflex neuroses—headache, migraine, localized muscular spasms, chorea, minor epilepsy, gastric neuroses and neurasthenia—with illustrative cases. He concludes:

1. The eye and the nose are undoubtedly most important factors in the etiology of reflex neuroses, and should, therefore, be carefully examined and positively excluded before beginning a search for other causes.
2. Ocular and nasal reflexes possess many manifestations in common, which should be carefully differentiated at the earliest possible moment.
3. Eyestrain, whether from ametropia, subnormal accommodation or muscular imbalance, should be carefully corrected in order to eliminate the eye as a causative factor.
4. An atrophied eyeball, with contracting ciliary scar, should be enucleated.
5. Pressure contact in the nose will always excite some reflex disturbance when any hyperesthetic area is impinged on, and should, therefore, be eliminated.
6. Every obstruction to free breathing should be removed.
7. Recurrence of any reflex neurosis demands re-examination and renewed search for the original exciting cause.

15. **The School Child.**—Van Derslice says that the development of the intellectual capacity is only a small part in child education. The development of character and of physical welfare is also vastly important. Some of the contributing factors of stress and strain of the school child lie in the child, such as hereditary dyscrasia, physical, mental and moral conditions, home environment, the artificial life in large cities, disorders of nutrition, etc. In the school are found conditions of school buildings, sanitation, improper desks and seats, lighting, ventilation, type and paper of text-books, lack of recreation, hours of confinement, lessons, schedule, etc. Physical and mental lassitude should not be dogmatically attributed to the amount of work. Investigation should be made in the other directions also. He discusses the hygiene of the home, food, regular duties and responsibilities, employment, lack of harmony between the parents and the public school, social distraction during school life, sanitation of schools, infectious diseases and curriculum, and says that the over-

crowding of the curriculum is due to three causes: 1, every child must take all the work, regardless of personal or individual need; 2, whatever the last generation had must go into the curriculum of the present one; 3, domination by the colleges.

17. **Brachial Birth Paralysis.**—Osterhaus discusses the nature, pathology, varieties—upper, lower and total arm paralysis—diagnosis, prognosis and treatment of this form of paralysis. He considers that to wait at least a year or two years after the onset of the paralysis before operating would be entirely proper, as not only would the operative field be enlarged, but the danger of shock will be lessened. He repeats Taylor's description of the operative technic. It occurred to him that the application of the principle of bridging nerves might be of service by allowing scar tissue to take the place of the catgut strands commonly employed. To this end the nerve junction was carefully lifted on two fingers, the nerve sheaths having been previously split up for a considerable distance above and below, and with a fine sharp tenotome the nerve fibers constricted by the cicatricial bands were thoroughly dissociated. Cargile membrane was then applied loosely and the wound closed. The return of function which followed was almost startling in its rapidity. The theory that the regenerating axis cylinders will use the strands of degenerated nerve fibers and scar tissue as bridges on which to extend themselves, similarly to vines on wire, certainly seems sound, and it only remains to prove or disprove this theory in actual practice. He urges a thorough trial of this method in all cases of nerve injury.

22. This article was commented on editorially in The Journal, Oct. 3, 1908, p. 1159.

23. **Influenza and Influenzal Pneumonia.**—Davis arrives at the following conclusions:

1. In many epidemics of clinical influenza or grip, the influenza bacillus plays little or no part as an etiologic organism.
2. These epidemics appear to be due to a variety of organisms—the *Pneumococcus, Streptococcus pyogenes, Streptococcus mucosus*, and *Micrococcus catarrhalis* being most commonly found in the secretions. An organism morphologically and culturally identical with meningococcus was found in one case.
3. Complications following these cases are often serious and usually due to *Pneumococcus, Streptococcus pyogenes* and *Streptococcus mucosus*.
4. The influenza bacillus is often found in so-called influenzal pneumonia, but not in all cases. It can not be considered the primary cause. An abundant mixed bacterial flora is characteristic of the respiratory secretions in these cases.
5. Influenza bacilli are commonly found in a great variety of infections.
6. Experiments both on animals and on human beings demonstrate that these bacilli possess pathogenic properties. They are often, or at least sometimes, non-virulent as they occur in the secretions.
7. As secondary invaders they undoubtedly unfavorably influence other primary infections.

24. **Heart Block.**—Hewlett reports clinical observations which lead him to the following conclusions:

1. Ventricular contractions may cause waves on the jugular pulse with little or no effect on the apex beat.
2. Such contractions may be followed immediately by normal contractions without a diastolic period.
3. The right ventricle may begin its contraction distinctly later than the left.
4. In his own case these were largely strophanthin effects.
5. They are probably to be interpreted as instances of intraventricular heart block.

26. Abstracted in The Journal, June 6, 1908, p. 1930.

27. **Volume and Specific Gravity of Organs.**—Olsho recommends for the determination and accurate registration of the size of any organ, the following plan: Each organ as it is removed is submerged in a vessel filled with water to a level at which an overflow is provided. The water displaced overflows into a container graduated in cubic centimeters; the amount so obtained represents the volume or displacement of the organ in cubic centimeters. The organs are weighed in grams; the weight divided by the displacement, equals the specific gravity. The heart is submerged opened or unopened. A "voluminous" emphysematous lung is pressed beneath the surface of the water by a rod thrust into the bronchus. Olsho gives results from 100 postmortems at the Philadelphia Hospital, in relation to the heart, kidney, liver, spleen and lungs, to determine the practical value of the method suggested, and on these examinations he bases the following conclusions:

1. Parenchymatous degeneration lowers the specific gravity of organs proportionately to the degree of parenchymatous change.
2. Fibrotic change, while diminishing the volume of the organ, also raises its specific gravity proportionately to the amount of fibrosis.
3. Although useful in systematic studies of all organs, the specific gravity records are most striking in pulmonary affections.

28. **Ocular Tuberculin Reaction.**—Frissell and Van Ingen classify the results of other observers and report the results of their own experiments in 166 cases, from which they reach, in brief, the following conclusions:

1. In apyrexial cases the test has the same value as the subcutaneous method. In pyrexia the conjunctival method is alone applicable.
2. So specific a reaction as the tuberculin probably indicates in all cases the presence of tuberculosis.
3. The method appears to be particularly helpful in the case of children.
4. In cases without symptoms it is perhaps safer at present to accept the reaction as a danger sign.
5. A negative reaction by no means excludes a diagnosis of tuberculosis.

31. Abstracted in The Journal, July 4, 1908, p. 71.

32. **Superiority of Primary Over Secondary Cesarean Section.**—Warren discusses the paper by Reynolds of Boston at the 1907 meeting of the American Gynecologic Society (*Boston Medical and Surgical Journal*, Oct. 31, 1907, abstracted in The Journal, Nov. 16, 1907, p. 1714), in which he favors delivery by an elective abdominal section, rather than by a difficult intrapelvic operation, either at term or prematurely. Warren, while agreeing that deformities of the pelvis, absolute in fractions of inches or centimeters, or relative in connection with large children, are much more frequent than is ordinarily expected, asserts that it is not to be expected that the general practitioner will spend much study over fractional differences in pelvic diameters. The refinements of pelvimetry and facility in the use of complicated pelvic calibrators are for the expert. From a fairly extensive acquaintance with the obstetrical work of the general practitioner, he is convinced that most of the mishaps of delivery are due, not so much to simple pelvic insufficiency as to failure to recognize, before operation, malpositions of the presentation or that the child is too large for even a normal pelvis. The conscientious practitioner will remedy either of these two mistakes by careful study of conditions and environment; the other man will never rise to the level of science or art, and will always be content with brute force.

34. **Infarction of Renal Cortex in Pregnancy.**—Klotz gives the clinical history and postmortem findings in such a case,

and compares them with three other reported cases of a similar character and discusses the causation. He does not agree that an endocarditis was the causative factor in his case, but believes from the clinical evidence of rapidly developing suppression, and from the microscopic picture of the granular thrombi, that the thrombosis occurred simultaneously in all the renal vessels, as a result of certain metabolic changes of secretion in pregnancy. What these changes are he can not venture to say, but, as a result, there has occurred a dissolution of the red-blood cells in this particular part of the arterial tree, and the débris—and possibly the agglutination of these cells—has led to a plugging of the smaller arteries. To be exact, this process is rather an embolic one, coupled with thrombosis, and is similar to the agglutinated red-cell thrombosis in the liver. Evidence is lacking to assert that an increased coagulability of the blood had been produced in this portion of the arterial system and had led to a blocking of the cortical arterial stream.

35. Abstracted in The Journal, Oct. 24, 1908, p. 1458. Also published in the *Journal of Obstetrics and Gynecology of the British Empire*, September, 1908.

38. **Causes of Abortion.**—Taussig points out that the causes of abortion are usually considered in an unsystematic and illogical way. We must endeavor to differentiate between conditions of the uterus which predispose to such an expulsion of the ovum, and conditions which excite the uterus to get rid of its contents. He proposes the following classifications. The predisposing causes are:

1. Increased sensitiveness to nerve irritation (temperament, frequent abortions, menstrual period).
2. Greater tendency to placental thrombosis (inflammation of endometrium, congestion).
3. Lessened resistance to expulsion (cervical tears or amputation).

The exciting causes are:

1. Mechanical Irritation: (a) transmitted (blow, fall, dancing, railroad journey, lifting heavy objects, constipation); (b) direct, (1) to outside of uterus (adhesions, malposition, tumors, examination, laparotomy); (2) to inside of uterus (instruments, hemorrhagic exudates, hydramnios, tumors).
2. Thermic Irritation: (a) general (sea bath); (b) local (hot douche, sitz bath).
3. Toxic Irritation: (a) chemical toxins (ergot, carbon dioxid, lead-poisoning); (b) bacterial toxins (maternal smallpox, measles, etc.); (c) placental toxins, hyperemesis, chorea, eclampsia.
4. Nerve Irritation: (a) psychic (fright, pain, shock); (b) reflex (external genitals, breast, nose).
5. Death of Fetus: (a) congenital inanition (illness of parents, alcoholism, too frequent coitus); (b) congenital deformities (primary in ovum, amniotic adhesions); (c) interference with nutrition: (1) maternal (anemia, tuberculosis); (2) placental (mole degeneration, thrombosis); (3) umbilical (twisted cord, true knot, constrictions); (d) infectious diseases (syphilis, smallpox, typhoid, pneumonia, etc.); (e) hyperpyrexia.

41. **Essential Edema in Children.**—Schwarz discusses the prevailing theories as to the physiologic and pathologic factors which enter into the formation of both local and general edema. He discusses only those varieties of essential edema which he has personally observed, and reports five cases, the last, one of acute circumscribed edema. Many cases of this condition are of unknown origin and have to be classed as idiopathic. As to symptoms, the skin may be normal, but usually there is a pinkish white glassy appearance, moreover, the parts are elastic. The involvement of the upper respiratory passages interests the pediatrician and the laryngologist. In the nose the disease resembles hay fever in sudden onset, but there is little sneezing and no excessive secretion. In the larynx, it constitutes one of the dangers of the disease, the attacks of edema usually coming on during sleep, but sudden dyspnea may occur at any time. In the lungs it may give rise to acute edema. As abdominal symptoms, colic, vomiting and diarrhea are noted. The kidney may be involved, slight traces of albumin and even blood being present. Transient aphasia may be due to the transient edema. Schwarz discusses its differentiation from giant urticaria, Osler's symptom-complex of exudative erythema with visceral lesions, exophthalmic goiter, purpura and the hysterical edemas. The prognosis is usually good, edema of the larynx being the only cause of death. Abdominal symptoms are often severe. Morphin seems to be the only thing that helps. Scarification and application of suprarenal extract to the edematous parts is recommended in edema of the larynx. Tracheotomy may be necessary. Avoidance of predisposing articles of diet and relief of constipation are prophylactic measures.

46 *Adjustment of Paramecium to Distilled Water and Its Bearing on the Problem of the Necessary Inorganic Salt Content. J. F. Daniel, Baltimore.

42. **Excretion of Kreatinin and Kreatin.**—It has been usually believed that since kreatinin and kreatin are closely related chemically, one might easily be transformed into the other in metabolism, and that the kreatinin of the urine might be derived either from kreatin ingested in meat or formed in the muscle. Shaffer, using Folin's method, has estimated the kreatinin and kreatin in the urine in both normal and pathologic conditions. He reaches the following conclusions:

1. The amount of kreatinin excreted by strictly normal individuals is between 7 and 11 mg. kreatinin-nitrogen per kilo of body weight. The amount excreted by any one individual is constant, not only from day to day, but from hour to hour; and the amount is independent of the volume of urine as well as of the total nitrogen.
2. The kreatinin excretion [illegible] usually low, varying from the normal to [illegible] per kilo of body weight in twenty-four [illegible] kreatinin-nitrogen per kilo—the kreatinin coefficient—shows a direct parallelism with the muscular development or strength, or "muscular efficiency," of the individual.
3. Kreatinin is not an index of the total endogenous protein katabolism. Individuals with exophthalmic goiter and others in whom the total endogenous katabolism is probably much increased may excrete very little kreatinin.
4. Kreatin is derived from—and its amount, expressed in milligrams per kilo body weight, is an index of—some special process of normal metabolism taking place largely, if not wholly, in the muscles. On the intensity of this process appears to depend the muscular efficiency of the individual.
5. The kreatinin excretion is slightly increased in acute fevers, and in this condition does not run parallel to the muscular efficiency of the individual.
6. Kreatin is not a normal product of endogenous metabolism, and is not present in normal urines, unless the individual has taken kreatin with the food.
7. Kreatin may be excreted by individuals with acute fevers, in the acute stages of exophthalmic goiter, in other conditions in which there is a rapid loss of muscle protein, and by women during the postpartum resolution of the uterus.
8. The source of endogenous kreatin is probably the kreatin of the muscle tissues, and its appearance in urine probably indicates that muscle protein is being absorbed.

46. **Adjustment of Paramecium.**—Daniel's investigations indicate that the destructive action of distilled water on animal organisms is due to the sudden change in media. Great difference in the power of resistance to this action is shown by different organisms. Organisms transferred gradually lived for days without food in a purer water than it took to kill the control animals suddenly subjected to it. The difference in resisting power may explain the differing results reported by various observers. The adjustment of animals to the conditions under which they live, and their power of becoming adjusted by a slow process to new conditions is one of the most important matters requiring consideration in dealing with the effects of environmental agents.

56. **Oration on Medicine.**—Emmert discusses the recent advances in medicine, the crusade against venereal disease, and the treatment of mental defectives, degenerates, criminals, etc.

57. **Peritonitis.**—LaForce discusses the anatomy of the peritoneum, the pathology and bacteriology of peritonitis, and the question of drainage and material. He considers the following helpful processes of inflammation: Hyperemia, serum exudation, fibrin formation chemiotaxis, leucocytosis, lymphangitis and thrombosis, and granulation tissue, and shows how they offer indications for treatment. He also discusses the part played by the omentum, the peritoneal endothelial cells, and the antiperistaltic power of the large intestine, in relation to the process of absorption.

58. **Toxemia in Pregnancy.**—Herrick, in summing up his paper, says that the disturbances of pregnancy are with few exceptions caused by toxemias. The toxins have their origin in the increased metabolism of the mother, the enormous waste of a rapidly growing child, and in all probability partially in the chorionic tissue of the placenta. The normal woman with her reserve capacity to deal with excess of waste passes these ordeals unscathed. Her less fortunate sister has less capacity and is overwhelmed by the excess of toxic materials. Just where the failure lies is a matter of debate, but recent observations and experiments point to a failure of the anabolic and catabolic processes in the body which are carried out by ferments. In other words, there is a failure in the production of the necessary ferments to break down these wastes for elimination. This failure is not due primarily to disease of the kidney or liver as is commonly believed, but these organs suffer with all others from the toxemias. Rational treatment of these conditions should look to the correction of metabolic faults and the increase of the tissue ferments, the free and rapid elimination of wastes by occasional doses of mercurials followed by large doses of magnesium sulphate together with a free laxative effect, produced preferably with magnesium sulphate, which may be given in small doses every morning or even in dram doses two or three times a day with plenty of water. This, with plenty of water at all times, and possibly intestinal antiseptics, will relieve many patients. In diet the proteids should be reduced to the lowest possible quantity. Fruit and vegetables, with milk and cereals, should constitute the chief support of the patient. An exclusive milk diet is necessary at times. The facts that imperfectly developed or diseased thyroids are found in many cases and that extirpation of the thyroids in pregnant animals produces albuminuria and toxemias, would suggest the use of thyroid extracts. Care should be taken in their administration, since they are among the most powerful therapeutic agents known. Finally, the author believes that by careful observation and management eclampsia may be prevented.

California State Journal of Medicine, San Francisco.

October.

69 The Ocular Tuberculin Reaction. E. F. Glaser, San Francisco.
70 The Housing Problem. T. Coffey, Los Angeles.

61. **Anatomy.**—Tasker quotes a number of answers given at the state board examination to questions on anatomy, to demonstrate the distorted ideas of the human frame held by many practitioners. He has devised a plan of examining whereby the candidate could use his practical knowledge, instead of perhaps losing his bearings in descriptive terminology. To this end a rubber stamp was made of an outline cut such as those used for clinical records. The candidate was asked to outline the heart and liver on this cut. Tasker reproduces nine answers for ocular demonstration to the profession that there is something radically wrong in the teaching of anatomy and that the most practical questions in the whole examination bring forth absolutely staggering answers.

62. **Tuberculous Laryngitis.**—As a result of an analysis of 61 cases Pottenger arrives at the following conclusions:

1. When tuberculosis of the larynx is diagnosed early the prognosis is about the same as in tuberculosis of the lung when diagnosed early.
2. Chronic thickening of the larynx always calls for careful expert examination of the lungs, to determine the presence or absence of pulmonary tuberculosis, and if the latter is found, the evidence is strongly in favor of the tuberculous nature of the laryngeal lesion.
3. Local applications will not cure tuberculosis of the larynx. The cure comes through the patient's body fluids.
4. Tuberculosis of the larynx is not a separate disease, but a complication, and a rational treatment consists in the treatment of it as a part of a tuberculous process elsewhere, usually of the lungs.
5. Tuberculin and the other tubercle vaccines, intelligently administered, are of inestimable value in establishing immunity and bringing about a cure in tuberculous laryngitis.

63. **Aneurism of the Abdominal Aorta.**—Stratton concludes that the following points seem to be true in regard to direct, gradual, arterial closure in the treatment of aneurism of the abdominal aorta:

1. The sac can be filled with active or stratified coagula by that method.
2. The arterial tunics can safely endure the necessary manipulation and pressure.
3. Partial, rather than complete, arterial closure will ordinarily be the safest and most effective means.
4. The lumen of fully patulous arteries supplying the viscera and emanating from the sac, as well as the main blood current down the artery, can be maintained.
5. The general vitality of a proportion of patients afflicted with the disease is sufficient to endure the necessary operative interference.

73 and 74. Abstracted in The Journal, June 13, 1908, p. 2016.

76. An extensive article by this author on hospital construction appeared in The Journal, Sept. 21, 1907, p. 990.

78. **Ludwig's Angina.**—Pratt reports four cases in detail, in order to emphasize the lack of constitutional symptoms and the early and severe involvement of the air passages; the former appearing in no instance until after a longer time than usually suffices to end the disease one way or the other; in other words, the longer the disease lasts the more chronic its course, the greater probability of constitutional symptoms from a toxemia; but also the longer a patient lives the greater the chances of recovery. It seems but logical, therefore, to assert that death is due to respiratory involvement and that the part played by the infective agent from a constitutional standpoint is but secondary.

88. **Criminal Abortion.**—Rev. A. Biever explains and defends the position of the Catholic church, which prohibits the production of abortion under any circumstances whatever, even to save the life of the mother. In reply to the argument that, of two evils the lesser should be chosen, he replies that if the choice were between evils in the same order, then of course it would be lawful to choose the less But the choice is between a physical and a moral evil, and it is not right to do a moral wrong for the purpose of hindering a physical evil. While life may be taken in self-defense against an unjust aggressor, even in self defense it may not be taken against an innocent person, and this the fetus undoubtedly is. Further, he adds that if it is once granted that grave reasons may justify abortion, it will be found difficult to draw the line, and, he asks, Will the doctor who has destroyed fetal life on occasions when he deemed it legitimate practice, have the courage to resist on all other occasions?

91. **The Female Bladder.**—Perrilliat points out that if less attention has been paid by the gynecologist to the female bladder than has been paid by the genitourinary specialist to the male bladder, it is because the separation of the genital from the urinary tract in the female has made it less vulnerable and easier of recovery. On the other hand, its close anatomic relation with other organs and its peculiar relation with the pelvic floor, render it liable to injuries from parturition He describes the anatomy and its bearing on certain conditions of the bladder, and points out that the domestic habits of womankind are such as to encourage habitual over distension, and to predispose the organ to disease or derangement. The recumbent posture results in diminished pressure and is of great value in the treatment of diseases of the bladder. He points out the anatomic reasons for the importance of always emptying the bladder before making a manual exploration of the uterus or adnexa. In determining in a given case the association of pelvic disease with bladder irritability, the cystoscope is of inestimable value. Statistics show the association of the two conditions in nearly 70 per cent of the cases He insists on the importance of a vesical exploration in every case of a more than transient nature, and asserts that no harm can possibly follow the proper use of the cystoscope

92 **Country Practitioners as Medicolegal Experts.**—Ballowe asserts that the average country practitioner is not fit to pose as an expert when the life and liberty of an accused person is at stake Medical jurisprudence occupies but little attention in college teaching, and a graduate therefore is not fit to pose as an expert, unless by his own subsequent industry and experience he has acquired the requisite knowledge. This, save in a few individual instances, he rarely does, and Ballowe urges the country practitioner to accept no calls to give medical testimony unless he is thoroughly prepared to give it properly with the scant protection afforded by the court. It is a most pitiful sight to witness an incompetent or unprepared medical witness on the stand, being mercilessly flayed by a clever and skillful lawyer.

101 *Hydrocephalus of [illegible], with a Summary of Recent Cases of [illegible] by Antimeningococcus Serum J H Kr[illegible] Baltimore

96 **Epidemic Cerebrospinal Fever.**—This article is a descriptive account of the history, causation, pathology, histology, course and symptomatology, diagnosis, complications and treatment of this disease accompanied by a number of characteristic illustrations. Royer adds to his pessimistic view of the treatment a postscript in a much more hopeful tone based on the recent treatment of seventeen patients with Flexner's serum with only seven deaths.

97. **Lumbar Puncture.**—Burvill-Holmes describes the technic of the operation, contrasts the normal and pathologic spinal fluids, and discusses the value of cytodiagnosis in differentiating tuberculous meningitis from the epidemic variety. He believes that in cases of doubt, or when meningococcus on the one hand and the tubercle bacillus on the other can not be demonstrated, a cytologic estimation is of great advantage and should be made, particularly when we have at our command an operation so easy of performance and practically so free from danger, if the ordinary precautions are taken, as is lumbar puncture.

98. Abstracted in THE JOURNAL, July 4, 1908, p. 65.

99. **Meningococcic Meningitis.**—Churchill believes that with our present knowledge of Flexner's serum, it is our duty, given a case of meningitis, to do lumbar puncture, and if we obtain a cloudy fluid to inject the serum at once into the spinal canal, subsequent injections being determined by the results of the bacteriologic examination of the fluid. If this shows the presence of the meningococcus, the serum should be repeated every day for three or four days if necessary. If relapses occur, we should resort to the serum again.

5. **Puncture of Brain.**—Tillmanns says that puncture of the brain is indicated as a diagnostic in all cases when the diagnosis is uncertain. When injury or disease of cranial cavity or brain is evident, trephining is required. Therapeutic puncture is practiced for hydrocephalus, dropsy of ventricles and for injections. Tetanus antitoxin cranial injection has been rightly abandoned for subcutaneous or intravenous injection or into the spinal cord or nerves. For instance, in wounds to the hand, where tetanus is expected, Tillmanns recommends immediate injection into the exposed brachial plexus endoneurally. He describes the technic of aseptic puncture of the brain. As to site, he recommends puncture from above, through the frontal bone about 2 cm. from the central line and 3 cm. from the precentral fissure. The hollow needle must be pushed downward and backward, striking the ventricle at a depth of 5 to 6 cm. A ring or shield fitted to drainage tube will avoid going deep enough to injure the opposite wall. Subcutaneous drainage is most advantageous. The ventricle may also be punctured from behind from the occipital lobe. The posterior cornu is met with at a depth of 3 cm. if cranium is opened 4 cm. over protuberantia externa and 3 cm. to side of central line of skull. Direction should be forward and slightly upward.

8. **Cats as Plague Preventers.**—Buchanan follows up a previous article to insist on the importance of the cat as the best of all plague preventers.

10. **Appliance for Colotomy.**—Ingram describes an ingenious apparatus invented by one of his patients on whom colotomy had been preformed. It consists essentially of a metal box with a flange that can be attached to a body plate. At its dependent part it has a chute, at the end of which is fixed a rubber bag. The inventor is a busy traveling man and always carries two or three with him.

12. **Amebic Abscess of the Liver.**—Anderson recapitulates as follows the four principal reasons for the belief that there exists such a disease as amebic abscess of the liver:

1. Cases of dysentery characterized by the presence of amebas in the stools frequently develop liver abscess.
2. Patients with liver abscess admitted to charitable hospitals are frequently associated with dysentery with amebas in the stools.
3. Amebas are found in the interior of abscesses of the liver.
4. The experimental injection of *Entamœba hystolytica* into the bowels of cats and puppies has in some cases produced dysentery and liver abscess.

He discusses each of these in detail in relation to the statistics of 920 cases of dysentery at Port Blair, of which more than half the patients harbored amebas in their stools. Abscess occurred in less than 0.1 of all cases of dysentery, or 0.2 per cent. of dysentery with intestinal amebiasis, from which he infers that amebas in the intestines and stools, in Port Blair, neither foretold nor caused abscess of liver. The statistics also show that abscess of the liver occurs in less than 1 per cent. of cases of dysentery. That amebas are found in the interior of abscesses of the liver is undeniable, but is a very weak argument that they cause the disease. Experimental injection of amebas by mouth and rectum failed in Anderson's hands, to produce liver abscess. He concludes, therefore, that *Entamœba histolytica* in Port Blair and Eastern Bengal, at any rate, is not the important factor in the causation of abscess of the liver.

13. **Intestinal Amebiasis.**—Wenyon summarizes his article as follows: There is an ameba which is to be found in the human intestine, both in health and in disease, which reproduces asexually in the intestine and sexually in cysts, and which contains two, four or eight nuclei, according to the stage of development. These cysts escape to the exterior and

transmit the infection to other hosts. This ameba is not peculiar to man. In order to determine whether the ameba found in the tissues in dysentery and allied disorders is the same or a different species, it is necessary to study the developmental process; this has been done by Schaudinn, with the result that he describes two distinct species; but his results need confirmation.

14. **Prevention of Amebic Abscess of Liver.**—Further experience of ipecacuanha in the presuppurative stages of amebic hepatitis, confirms Rogers' contention that tropical liver abscess can thus be easily prevented. Four-fifths of amebic liver abscesses are free from bacteria and cocci when first opened, or postmortem if previously unopened. In cases of tropical liver abscess proving fatal after the open operation, infection with staphylococci is almost invariably found. The great majority of patients examined at the time of being dressed subsequently to the drainage show a similar infection, which it is almost impossible to prevent in damp hot climates. Postmortem evidence shows that, in half the number of patients, being 50 per cent. of the total operated on dying subsequently to the abscess being opened, conditions are found which almost preclude hope of recovery. In the remaining half, single, or practically single, medium-sized abscesses are found, which afford good hope of recovery under improved methods of treatment. By means of a flexible sheathed trocar, liver abscesses may be drained and repeatedly irrigated with quinin solution without the admission of air, with probably better results than the present Calcutta mortality of about 60 per cent. The ipecacuanha treatment should always be used after operation for liver abscess, to cure any latent amebic dysentery and to prevent further abscess formation.

15. **Tropical Liver Abscess.**—Bose says that ipecac in large doses in the presuppurative stage is sometimes followed by excellent results. He points to the effect of the use of cannabis indica in deteriorating the resisting power of the liver, and rendering it more susceptible to inflammation and suppuration.

18. **Mycosis Fungoides.**—Garceau is of the opinion that until we are more clearly informed of the nature of this disease the treatment should be tentative, and he is also firmly convinced that attention to the nervous system, to the general health and hygienic measures, is largely influential, as well as local treatment, in producing general benefit. Specific therapeutics depends on the discovery of a special organism.

19. **Solar Therapy of Lupus Vulgaris.**—Tomkinson, from the history of a patient treated by daily exposure to the sun's rays at Helouan, Egypt, recommends that where sun and other climatic conditions are favorable a trial be made of this method.

20. **Lupus Vulgaris.**—In regard to the local treatment of this disease, Lancashire believes that if a purely caustic treatment is decided on, the best drug at our disposal is pyrogallol. It must be pushed and a strong preparation used. He finds the 40 per cent. plaster superior to the 30 per cent., which he formerly used.

24. **Occupation Dermatitis.**—Gardiner makes the following deductions, based on 187 cases of occupation dermatitis at the Royal Infirmary, Edinburgh:

1. Most patients are attacked either a week or two after going to work for the first time or not until they have been employed a number of years.
2. Seborrhea and hyperidrosis, or precedent skin disease, increase the liability to attack.
3. Attacks are more frequent in hot weather, heat being a predisposing agent, even if nothing more.
4. The eruption is often made worse by the use of "patent" remedies.
5. Soaps are the actual provocatives in many cases, and in others aggravate an existing dermatitis.
6. The arms, hands and face are most frequently affected.
7. Some disturbance of the general health may determine the onset of the dermatitis or lead to its extension.

40 Three Cases of Congenital Heart Disease. G. Carpenter.

39. **Urinary Tuberculosis in Children.**—Leedham-Green says that instead of regarding it as a relatively rare disease, which, when present, is difficult to alleviate and hopelessly incurable, we now know that urinary tuberculosis is exceedingly common, and when recognized early and the primary focus removed is of distinctly good prognosis. Systematic examination of urine will reveal tubercle bacilli in many unsuspected cases. If in doubt, the opsonic index and the ocular and cutaneous reactions should be resorted to. He notes the weak points of these tests, and says that the only reaction giving a clue to location of infection is that of subcutaneous injection of old tuberculin. He insists on the importance of cystoscopy for estimating involvement of the bladder, and says that it may be practiced in the youngest girl and in boys over 8 years. Chromocystoscopy—the injection of carmine blue subcutaneously, and observing its excretion through the cystoscope—is a valuable adjunct. Where numerous tubercle bacilli and transitory hematuria exist without indication of site of trouble, a good substitute for exploratory nephrotomy is to expose the ureter subperitoneally by a small incision in the abdominal semilunar line, open it by a small longitudinal cut, insert a fine urethral catheter, and collect the urine separately. A fine stitch closes the opening in the ureter, which is dropped back to place and the wound is drained for a day or two.

41 *Heart Lesions Among the Natives of Sierra Leone. H. E. Arbuckle.

41. **Heart Lesions.**—Arbuckle, as the result of an examination of apparently healthy natives of both sexes in Sierra Leone, finds that in a country where the cause we are accustomed to regard as by far the most potent, namely, acute rheumatism, is certainly not operative, heart disease is, nevertheless, very prevalent. The most obvious deduction is, that even in countries where acute rheumatism is of such prevalence as to overshadow in importance the other competent causes of cardiac lesions, these latter should never be forgotten or neglected by the practitioner, in respect of prophylaxis, diagnosis or prognosis.

42 *Treatment of Certain Puerperal Infections with a Continuous Current of Oxygen. P. Reynier.

42. **Continuous Oxygen Douche in Puerperal Infection.**—Reynier reports in detail four cases of severe anaërobic puerperal infection in which marked improvement followed the use of a current of oxygen allowed to flow continuously into the uterus, through a recurrent catheter. The gas is admitted very slowly, avoiding all pressure, and the catheter is left permanently in the uterus, connected by a tube as needed with the oxygen tank. In the first case reported, the patient was much prostrated, six days after her confinement, the temperature being 40 C. (104 F.), and the lacerated perineum and cervix were covered with diphtheroid false membranes. The uterus was rinsed out with hydrogen dioxid morning and evening, followed by an iodized injection, and this by the continuous oxygen treatment. The temperature dropped to normal for part of the next day, and in five days the patient was well on the road to recovery. The results in the other cases were equally convincing. This oxygen treatment has been used in Thiriar's service at Brussels for some years, and he has reported good results from it, as mentioned in these columns, Sept. 29, 1906, page 1059.

45 *The Ethereal Sulphates in the Urine in Gastrointestinal Autointoxication. (Les sulfo-éthers urinaires.) R. Brunon and M. Guerbet

43. **Association of Tuberculosis with Syphilis.**—Sergent protests against the prevalent idea that this combination is exceptionally grave. On the contrary, specific treatment of the syphilis is liable to have a favorable influence on the tuberculous process. When a tuberculous individual contracts syphilis, the outlook is grave, but when a syphilitic develops tuberculosis, thorough mercurial treatment is liable to improve and even to cure the tuberculosis. Potassium iodid must be strictly avoided as it is liable to induce congestion and prove dangerous. The tuberculous and syphilitic processes may develop side by side without any reciprocal influence, and it is by no means exceptional to observe the tuberculous process assume an unusually mild fibrous form in these conditions. This is favored by treatment with lime, according to Ferrier, and general tonic measures. Sergent's research has shown that the lesions are never hybrid, but the syphilis may prepare the soil for tuberculous invasion.

45. **The Ethereal Sulphates in Gastrointestinal Autointoxication.**—Brunon and Guerbet, in previous articles, have called attention to the important information to be obtained from the study of the proportion between the ethereal sulphates and the total nitrogen in the urine. The details of fifteen cases are tabulated as observed during a long period. In every case as the signs of autointoxication diminished under dietetic measures, the quotient of the ethereal sulphates divided by the total nitrogen grew lower, and clinical improvement or complete cure followed—this train of events proceeding always in the same order. This quotient ranges between 1 and 1.4 per cent in normal conditions, but in autointoxication it increases to 3 and in extreme cases to 6 or 7 per cent. The proportion of the sulphates may decline, while the total nitrogen remains high.

49 *Paravertebral Triangle of Dulness. Grocco's Sign. (Du triangle de matité paravertébrale et son peu de valeur séméiologique chez l'adulte.) M. Roch and R. Dufour.

49. **Diagnostic Unreliability of Paravertebral Triangle of Dulness.**—Roch and Dufour express amazement that those who have written on the subject of Grocco's sign never seem to have examined for it in physiologic conditions. They state that it is an ordinary physiologic phenomenon with no diagnostic or differential value. The resonance along the spine is normally reduced because of the presence in this locality of the peculiarly thick dorsal muscles filling what they call the costovertebral groove. The soft parts are 1 cm. thick at the fifth dorsal vertebra; 2 cm. thick at the seventh; 3 cm. at the ninth and 3.5 cm. at the eleventh, measured just outside the spinous processes. An inch beyond they grow much thinner. This is the cause of the dulness observed, they say, and in pathologic conditions it is merely concealed by the pathologic condition on the diseased side, but its persistence on the sound side has no differential importance—it can be found just the same in the healthy. The above remarks apply exclusively to adults; the authors have not studied the sign on children.

50. **Operation for Umbilical Hernia.**—An illustrated description is given of Lexer's technic. After resection of the sac, a purse-string suture is taken through all the soft parts around, below the skin. The hernial opening is then sutured, after which the purse-string suture is drawn up and tied. The aponeuroses of the rectus muscles are then sutured above and below the purse-string suture, after which the skin is sutured. This technic excludes the possibility of infection, and reduces the liability to hemorrhage, owing to the minimal area of the wound, while the entire operation can be completed in a very few minutes—possibly under local anesthesia alone.

54. **Surgery of the Stomach.**—Janssen reviews the experiences with operations on the stomach at Witzel's clinic at Dusseldorf, 1903-1907: There were 49 cases of cancer, with operative treatment in 44, and 37 operative cases of non-malignant stomach affections. This material is analyzed in detail and the final outcome compared with the reports from other clinics. Loss of weight proved an important aid in the diagnosis of cancer in the dubious cases; if the weight continues to decline, exploratory laparotomy should be advised, even if the other symptoms are vague. Stumpf advises resection, as the results are better with this, even as a merely palliative operation, than from gastroenterostomy alone, and the mortality of 9.5 per cent. is so low that it should not turn the scale against it. Gastroenterostomy is liable to give good results with a slow-growing cancer, but with the rapidly growing neoplasms, gastroenterostomy or jejunostomy merely relieves the patient without lengthening life. Carcinomas which have caused symptoms for a considerable time before operation often give better permanent results than those which necessitate operation early. The latter generally belong to the extra malignant, rapidly growing cancers. In the cases of perforation of an ulcer in the stomach or duodenum, 50 per cent. of the patients operated on were cured. Excision of the ulcer in the simple cases, supplemented by gastroenterostomy, gave good permanent results, as also resection in the cases of non-malignant stenosis of the pylorus. Gastroenterostomy plus a plastic operation on the pylorus failed in 33 per cent. of the cases of benign stenosis of the pylorus.

56. **Transplantation of Periosteum in Treatment of Bony Ankylosis.**—Hofmann states that the functional results are still good in the case he reported in 1906, in which bony ankylosis of the elbow was cured by chiseling the joint to its original shape and then covering the cut surfaces with a flap of periosteum taken from the patient's own tibia. He has since undertaken experimental research to determine whether the implanted periosteum retains its specific properties and whether this does not contribute to the excellent outcome. He has also applied the same treatment in four additional cases of bony ankylosis, and this experience has demonstrated, he says, that the implanted periosteum serves to prevent further development of ankylosis and of osteophytes, the periosteum providing the natural barrier for bone growth, thus interposing the one effectual obstacle to formation of callus and the growing together of the bones. It also seems to promote the adaptation of the new joint surfaces to the functional demands—in short, the periosteum seems to be the main factor in the restoration of normal function in the joint. The best results were obtained in the cases with comparatively

little cicatricial change in the capsule and tissues around the joint. The anterior surface of the tibia seems to be the best location for taking the flap of periosteum, care being observed in cutting it to retain the osteoblast layer intact. The tibia does not suffer by its removal, and the flap never became necrotic in any of his tests or clinical experiences. In each case, the joint was immobilized in a cast for several weeks, after which active and passive exercises were begun, the patient being urged to use the arm naturally as much as possible, and thus gradually to ensure complete restoration of function.

57. **Experimental Hyperemic Treatment.**—Graff devotes nearly a hundred pages to description of extensive experimental research with constriction and suction hyperemia at Innsbruck. Among the other results reported are that a fatal dose of strychnin could be injected into the limb of the animal below the constricting band, without injury, and that absorption of diphtheria and tetanus toxin was much delayed, but the toxin finally proved fatal. The serum accumulating below the constricting band on a human limb does not seem to contain any bactericidal substances effectual against staphylococci and streptococci, but the serum from rabbits, under the same conditions, has a marked stimulating action on phagocytosis, reducing the number of germs to less than one-fourth per thousand. He thinks that this stimulation of phagocytosis is the secret of the benefit of hyperemic treatment.

59. **Attempt to Influence Chronic Nephritis by Serotherapy.**—Casper and Engel describe in detail the treatment with serotherapy of eleven patients with chronic nephritis. The results proved that their technic is harmless, and that the general health of the patients showed marked improvement during the serum treatment, while the edema visibly subsided. In one case, the elimination of albumin and tube casts ceased entirely, while in others the amount only was reduced, and in a few no change was observed. They explain these variable results as due to the fact that the serotherapy is unable to restore to normal the already injured elements in the kidneys, but it keeps the functionally intact organs in good condition, and protects them against further ravages of the disease. The nephritis was in a pronounced form in all the patients thus treated. The curative serum was derived from a rabbit that was injected once or twice a week, for eight or ten times, with from 25 to 30 c.c. of serum obtained from 50 or 60 c.c. of the patient's own blood, set aside to clot. The serum was heated several times to 58 C. (136 F.) before being injected into the rabbit, and a separate rabbit was used for each patient. Blood was then drawn from the rabbit and the serum was mixed with 0.5 per cent. carbolic acid and injected into the patient in small amounts repeatedly. After the patient ceased to respond with a reaction to this rabbit serum, normal human or animal serum was used. Besides the specific antibodies generated in the rabbit in response to injection of the patient's own serum, the course of treatment is thus completed by supplying normal complement in serum from a healthy human or animal. The premises on which this method of treatment is based are described at length.

60. **Pneumococcus in Blood in Pulmonary Tuberculosis.**—Panichi reports that the pneumococcus was found circulating in the blood in four out of thirty tuberculous adults, without giving rise to any disturbances, apparently entirely latent. There was no history of pneumonia in any instance.

61. **Diabetic Lipoidemia.**—This communication from Grocco's clinic at Florence describes a case of diabetes in a boy of 13 whose blood contained excessive proportions of fat. The cerebrospinal fluid was opaque and milky and the blood also opaque and whitish, while the urine contained 35 gm. of fat in the twenty-four hours. The child succumbed in coma in the fifth month of the disease. The blood drawn during life contained in 100 gm. of ether extract, 94.170 parts total fat; 3.938 parts cholesterin, and 1,892 parts lecithin in 100,000 parts.

63. **Invisible Virus of "Three-Day Fever."**—Doerr is inclined to believe that the brief febrile affections known as dengue, summer fever, Shanghai fever, or by similar local terms, are in reality all of the same nature. In lower Austria such a sickness is prevalent during certain seasons. On account of the extreme collapse and depression it is popularly called "dog sickness," and is officially known as "endemic catarrh of the stomach." The syndrome is much like that of dengue. The government sent a commission in charge of Doerr to study the disease and means of prevention, and he has succeeded in tracing it to a virus which is transmitted by a gnat, the *Phlebotomus papatasii*, a small blood-sucking insect. The virus is in the patient's blood during the first day of fever but vanishes from the blood early. After the insect takes up the virus a week or so has to elapse before it can transmit the disease. Doerr infected a number of the gnats and by keeping them alive in large cages of fine organdy muslin, was able to infect three or four medical volunteers, even when the gnats were carried to Vienna from Herzegovina. He also infected four out of eight young soldiers who submitted to the test, the gnats being carried from the endemic spot to a region where the disease was never known to occur except as imported. Grassi published last year a work on these insects. The prevalence of the "three-day fever" corresponds with what is known of the localization and seasons of the phlebotomus.

67. **Scarlet Fever.**—Rubens has noticed that the severity of the sore throat, in every case of scarlet fever in his experience, invariably was proportional to the severity of the disease and the gravity of the prognosis, especially in regard to the complications. He has found that by keeping the process in the throat under control it is possible to attenuate the infection and ward off complications. Direct local applications with a brush are liable to be too superficial to do any good, or, if applied vigorously, may abrade the surface and open new portals for infection. Gargling is also too superficial in its effects, and it is difficult to get children to rinse out their mouths effectually with an antiseptic mouth wash. He has derived the greatest benefit from direct insufflation, through a straight tube, of a mixture of equal parts of sodium sozoiodolate and sulphur. It is necessary to repeat this insufflation every hour, day and night, to have it do any good, and he insists on this when he sees that the throat process is assuming a progressive character. He continues this local application until the ulcerations are circumscribed and the mucus production has ceased. As the throat process becomes attenuated under the influence of this local treatment, the general symptoms subside, and he has never had otitis develop or phlegmon in the maxillary glands under it. In a few instances otitis developed a week later, but this, he states, must have been from infection by way of the blood, and the otitis was always mild and rapidly subsided after paracentesis. The kidney complications must be warded off by strict dietetic measures, avoidance of all nitrogenous foods and alcohol, and reliance on milk as the main article of diet. During a very tempestuous onset of the infection, when there is danger of heart failure, he sometimes gives large doses of alcohol to tide the patient

past this crisis, but after this he forbids alcohol in any form. He keeps his patients in bed for four weeks. His careful examination of long series of scarlet fever patients has failed to reveal the diphtheria bacillus in the throat in any instance.

70. **Origin and Treatment of Pernicious Anemia.**—Reicher's communication issues from Kraus' medical clinic at Berlin, and describes a method of treating pernicious anemia based partly on the discovery of a hemolysin in the blood in this affection and partly on theoretical reasoning and laboratory experiments, as he describes in detail. His assumption is that the cholesterin in the body has the physiologic function of binding a complex hemolysin which is found in the blood normally. Lack of the cholesterin would naturally be followed by the accumulation of the hemolysin unrestrained, and this would be followed by hemolytic destruction of the blood, such as is observed in pernicious anemia. A 3 per cent. solution of cholesterin in olive oil (prepared with heat) neutralizes the hemolysin in the test tube and in experimental research, and it has given promising results in the clinic. He flavors it with a few drops of peppermint, and has the patients take about 100 gm. (a little over 3 fluidounces) every day. The mixture was taken readily by the patients, and the effect was very good in three of the four cases reported. The first patient was a woman of 40, and the stormy onset of the severe pernicious anemia was accompanied by dyspnea, ascites, pleural effusion and edema; reds, 750,000, and hemoglobin, 18 per cent. After the cholesterin had been taken for one week, the reds had increased to 1,750,000 and the hemoglobin to 30 per cent., and in the course of three more weeks to 50 per cent., while the other symptoms had disappeared, and the patient had increased in weight, although the spleen was still palpable. The cholesterin was kept up for seven and a half weeks, after which arsenic was given. The improvement lasted for some months, when the anemia syndrome recurred and proved fatal. In another case marked improvement was obtained, the reds increasing from 1,000,000 to 2,300.000, and the hemoglobin from 20 to 40 per cent.; in still another from 3.000,000 to the normal figure and the hemoglobin from 30 to 40 per cent. In the fourth case no benefit was apparent from the cholesterin, but a preparation of arsenic gave good results. He urges others to try this cholesterin oil in cases of pernicious anemia and possibly also of paroxysmal hemoglobinuria and eclampsia. In a certain proportion of such cases the cholesterin may respond to the causal indications, as the trouble may be the result of a lack of this substance in the organism and consequently loss of one of its most potent defensive factors. The literature on the subject is reviewed in detail, especially Kyes' research on the hemolytic prolecithid of cobra venom and the corresponding toxolecithid —both of which are bound by cholesterin, while animals can be rendered immune to the cobra lecithid by preliminary treatment with cholesterin.

79 *The Viscosity of the Blood. (Viscosität des Blutes.) F. Blunschy.

71. **Bitemporal Hemianopsia Succeeding to Epilepsy.**—Vogt reports a case of typical bitemporal hemianopsia discovered after eight years of some impairment of vision. The patient was a woman of 48, who between her twenty-third and thirty-sixth year had suffered from severe epileptic seizures but had had none since then. The symptoms indicate the existence of a tumor compressing the center of the optic commissure, perhaps enlargement of the hypophysis or some other lesion in the vicinity of the sella turcica. This lesion was probably responsible for the epilepsy, as also for the vertigo and headache still observed at times.

73. **Epidemic of Ringworm and Its Control.**—When the epidemic of ringworm was discovered a central office was opened for free examination and treatment, and 243 suspicious cases were examined, with positive findings in 45. Before the intended Roentgen equipment for treatment was installed, it was found that the affection differed from the ordinary type; the scalp was inflamed, there were efflorescences on the skin in 32 of the 45 cases, and one-fifth of the patients were adults. The cases seemed to be grouped by houses rather than by contact in the school and the affection was distinguished further by its comparatively ready curability. These features differentiated the affection from ordinary ringworm, confirmed by the discovery of the *Microsporon lanosum.* This parasite infests the domestic animals as well as man, while the microsporon of ordinary ringworm is confined to man. It was found that cats were the sources of contagion in a number of instances. In one family the cat was first affected and was killed, then various members of the family became affected, and finally a recently imported cat contracted the affection from them. The public was warned of the danger of contagion from cats; no other domestic animals showed signs of any affection of the kind. The main point in treatment is the removal of the hair over the affected area, and this it was found could be accomplished by keeping the region constantly moist, the infected hairs readily dropping out under the effect of the maceration, while the sound hairs did not seem to be affected by it to any extent. The parts were shaved and then a mild antiseptic paste or salve applied or a moist dressing with a 5 per cent. soda solution, covered with oiled silk or rubber to keep in the moisture. A cure was obtained in three or four weeks in some cases, while others required as many months, the average being seventy days. The brothers and sisters of those affected were kept out of school for two weeks.

74. **Scarlatinal Otitis.**—Nager has studied the statistics in regard to scarlet fever in the Basle canton since 1876. The figures show that scarlet fever is of a less severe type of late years, the mortality having dropped from 13.6 per cent. in 1876 to 1.9 per cent., of 1.335 cases, 1900-1905. Examination of 750 patients in the scarlet fever isolation hospital showed otitis in 22.8 per cent., although the affection was latent in some. Otitis media was found in 6.5 per cent. of all the cases. Acute catarrhal inflammation of the ear without perforation, developing early in the disease, always subsided, leaving no traces. In 2 cases the scarlatinal otitis destroyed both the labyrinth and vestibular apparatus. Children with adenoid vegetations seem peculiarly predisposed to severe scarlatinal otitis, even when the vegetations have been removed. There seems to be some special favoring factor in the conditions that accompany adenoid vegetations, probably some constitutional anomaly. In one family six children presented the severe form of scarlatinal infection, and two succumbed. It is impossible to prevent the spread of the exanthem or enanthem, but it is important to keep the nose and throat clean and disinfected, for which adrenalin is useful, followed by spraying with a 0.5 per cent. solution of hydrogen dioxid or a boric-acid solution, concluding with an oil spray. These measures repeated several times a day will keep the passages open and prevent stagnation of secretions.

76. **Extraction of the Arms According to Mueller's Technic.**—The principle of this technic for management of breech presentation is that by drawing one shoulder down lower than the other and working it through the pelvis the arm follows of itself. Instead of drawing the child vertically downward, as with the Deventer technic, when the shoulders are reached, the trunk of the child is drawn to one side which releases one

shoulder, which then appears at the vulva. Drawing the child by the feet in the opposite direction then releases the other shoulder, and the shoulders are thus delivered as with a vertex presentation. The aftercoming arms reduce the diameter between the tips of the shoulders and facilitate the maneuver better than when the arms are crossed on the chest. In extremely difficult labor with contracted pelvis, Mueller advises exerting forcible traction downward and then to one side, even if the child's clavicle snaps. This brings the shoulder past the brim and the clavicle may prove elastic enough to yield. There has been considerable discussion of late in regard to this Mueller technic, but Fellenberg's experience in two difficult cases was so favorable that he commends it in high terms.

77. **Typhoid Endemic from Bacilli Carrier.**—Huggenberg states that thirteen cases of typhoid occurred in a single family at different intervals in the course of thirty-one years, none with any apparent connection with typhoid epidemic or sporadic in the neighborhood, and notwithstanding the most scrupulous measures for disinfection and cleanliness and changes of residence of the family. Recent examinations have disclosed, however, that the mother, the first member of the family to have typhoid, thirty-one years before, still eliminates considerable numbers of typhoid bacilli in the stools, although apparently in perfect health. She was advised to disinfect her stools and urine for twenty-four hours before turning them into the drain, and to soak her bed and body linen also in a disinfectant solution before sending it to the laundry. She was also advised to keep away from the kitchen as much as possible, and to wash her hands frequently with a disinfectant solution.

78. **Laws Regulating Development of Secondary Affections with Apical Tuberculosis.**—Huguenin discusses the participation of the nerves, muscles, etc., in the cough and in aspiration of substances from diseased parts of the lung, showing how the development of secondary affections proceeds according to certain physical laws.

79. **Viscosity of the Blood.**—Blunschy has made a comparative study of the conditions in regard to the viscosity of the blood in 72 healthy and 52 sick persons under various conditions. Muscular exertion reduces the viscosity when severe and long continued, but increases it when mild and comparatively brief, even when there is much perspiration in both conditions. On the other hand, even very slight exertion in persons with cardiovascular or respiratory affections increases the viscosity. He ascribes the variations to the different proportions of carbon dioxid in the blood, and states that determination of the viscosity will thus reveal insufficiency in the circulation and respiratory ventilation of the blood. Caffein had a marked influence in rendering the blood more viscous, while camphor had the opposite effect. This opposite behavior of these drugs might profitably be borne in mind in prescribing them. In health the viscosity and hemoglobin percentage run parallel, but striking divergences are observed in various diseases.

83 *Treatment of Carbuncle. M. Grasmann.
84 Treatment of Eczema in Infants by Restriction of Salt. (Behandlung des Säuglingsekzems nach Finkelstein.) O. Mendelsson.

80. **Treatment of Pus Collections in the Pelvis.**—Tillmanns reviews the indications in the different forms of abscesses in the pelvis in men and in women, giving a number of minor points useful to bear in mind as to the best means of access, etc. In conclusion, he warns against any attempt at conservative treatment of tuberculous processes in the pelvic bones as not only absolutely ineffectual, but liable to aggravate the process. He adds further that operations on the soft parts are much less serious than when combined with resection of bone and he has consequently abandoned osteoplastic resections, even the temporary.

81. **Symptoms of Cerebellar Tumors.**—In the first of the two cases described, Gierlich found a sarcoma in the vermiform process of the cerebellum in a boy of 7. The symptoms had been distinguished by the high degree of cerebellar ataxia and intention tremor, especially the locomotor ataxia in the right arm and leg. While contemplating radical removal the patient died suddenly forty-eight hours after the exploratory operation, succumbing apparently to the effects of pressure on the centers in the medulla oblongata. The second patient was a woman of 28 with symptoms of a tumor in the cerebellopontine angle. As the symptoms were early accompanied with atrophy of the optic nerve and loss of the sense of smell, a second tumor in the anterior fossa was assumed, and no operation was attempted. Autopsy revealed, however, merely a single neurofibroma in the pontine angle originating in the glossopharyngeal nerve with much hydrocephalus. The latter was evidently responsible for the atrophy of the optic nerve. The circumstances indicated that the tumor might have been successfully enucleated.

83. **Treatment of Carbuncle.**—Grasmann makes a crucial incision and turns back the four flaps, cutting into sound tissue. The flaps are packed underneath with gauze dipped in a hot solution of boric and salicylic acid. This hot solution seems to be remarkably effectual in preventing hemorrhage and in promoting the expulsion of the necrotic tissue. The surrounding sound skin is protected with a salve against burning from the hot solution. A large moist dressing is applied, and the application is repeated in twenty-four hours, or, if the fever has subsided, not until the second day. He has never had occasion to make further incisions or to ligate any of the vessels.

95 Bicentennial of Albrecht von Haller. P. Richter.

87. **Posterior Basic Meningitis with Occlusion.**—Wimmer reports with autopsy findings a typical case of circumscribed non-specific posterior basic meningitis. In about 90 per cent. of the cases on record the disease occurred before the age of 3. The children were previously healthy except that in some cases there was preceding catarrh of the upper air passages or a prodromal otorrhea. About 16 per cent. of the cases on record terminated in recovery. Increasing somnolency and emaciation are unfavorable signs.

89. **Pernicious Anemia.**—The editors invited a number of clinicians to express their opinions in regard to the etiology and treatment of pernicious anemia. Among the replies received, His stated that more than half of all the cases resisted treatment. Eichhorst has frequently obtained good results from administration of arsenic kept up for many weeks, as also Naegeli. None had witnessed any benefit from a mountain climate, and none had any theory in regard

may do so, if they wish, and the advantages are explained to them. The change from the bed to the chair at the bedside for twenty minutes is insisted on with greater emphasis for very anemic and corpulent women, as the danger of thrombosis is greater in these conditions. The woman is helped out of bed very carefully, supported on both sides. The second time she is allowed to sit up for an hour or two, morning and afternoon. The general condition rapidly improves, catheterization of the bladder is not needed, and there are none of the pains in the back frequently complained of when the patient lies long in bed. He urges all who try this method to let him know their experiences, keeping the gynecologic and the obstetric cases separate, as he is collecting material for a comprehensive monograph on the subject for next year. Large numbers are not so important for his purpose as every single case in which untoward effects from the early getting up became evident. It has been his experience that working women are less subject to thrombosis than others, and he asks for the experience of others in this line. He also hopes that physicians who have not encountered cases of thrombosis will tell him to what they attribute this exemption from mishaps. In Holland, for instance, thrombosis is very rare.

125. **Tents are Superfluous.**—Herff states that he has not had occasion to use tents more than once in the course of the last seven years, although he has had to dilate the uterus in 800 cases, mostly for curetting. In a few cases he used gauze, but in all the others he preferred instrumental dilatation, and has never had a mishap, although the dilatation is done by some student, as a rule, under his supervision. He teaches that tents are unnecessary, except possibly with a hydatidiform mole.

128 **Ultimate Outcome of Cases of Tuberculosis* with and without Tubercle Bacilli in the Sputum. (Nogle Forhold verdrørende Tilfælde af Lungetuberkulose med og uden Tbaciller i Opspyttet.) T. Petersen.

127. **Treatment of Gastric Ulcer.**—Borgbjærg reviews the literature on the dietetic and medicinal treatment of gastric ulcer in the last few years, and relates his own experience. He agrees with Lenhartz and Thesen that the stomach mucosa is not sensitive, and that consequently the pains experienced are the result of the spread of the inflammation into the lymphatics or of traction on the parietal peritoneum from the contractions of the stomach. In treating an ulcer, therefore, it is important to avoid all articles of diet liable to promote peristalsis. For this reason also the food should be given in very small quantities; if there is much thirst water can be supplied by the rectum. Thesen allows nothing but lukewarm milk at first, a tablespoonful at a time, to a total of 250 c.c. (8 ounces) during the day, increasing an ounce each day during the first week; with one raw egg the second day, two the third, three the fourth, and so on, with nothing but the milk and raw eggs until the seventh day. At the same time he gives 10 gm. (150 grains) bismuth daily, believing that it diffuses into the lymphatics and arrests the lymphangitis. His experiences with thirty-five patients thus treated during the last two years have been favorable. Benefit is also liable to be obtained from olive oil, and Borgbjærg has had some striking results in this line, especially when bismuth is given with it, using a 7 to 10 per cent. suspension. In one of his cases hematemesis was the first symptom, followed by sudden pain in the stomach region, hypersecretion and morning retention. During the following six months the man lost constantly in weight, with no improvement under dieting and a course of Carlsbad water. He took 100 gm. (3 ounces) olive oil every morning, and the pains promptly subsided, while he gained nearly 25 pounds in weight and the suspicion of cancer was dispelled. The combination of olive oil and bismuth generally proves more effectual than either alone.

128. **Ultimate Outcome of Cases of Tuberculosis with or Without Tubercle Bacilli in the Sputum.**—Petersen tabulates the cases of pulmonary tuberculosis treated in three northern sanatoria and by Turban at Davos, with respect to the positive findings in the sputum just before and at the close of the sanatorium treatment. Examination from four to six years later shows that only 27.3 per cent. of those with bacilli in the sputum at that time have regained full earning capacity and only 9.7 per cent. are partially restored to work, while 55.5 per cent. have died in the interim. Those without bacilli show 73.4 per cent. with complete and 16 per cent. with partial restoration of their earning capacity, while only 4.7 per cent. have died. These figures include 2,623 patients with positive and 1,064 with negative findings in the sputum.

VOLUME LI CHICAGO, ILLINOIS, NOVEMBER 28, 1908. NUMBER 22

Address

THE NATURE AND CAUSES OF ECZEMA.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON CUTANEOUS MEDICINE AND SURGERY OF THE AMERICAN MEDICAL ASSOCIATION, CHICAGO, JUNE 2-5, 1908.

M. B. HARTZELL, M.D.
PHILADELPHIA.

Although eczema is of perennial interest to the dermatologist, it is not without some misgiving that I bring so trite and hackneyed a subject before this Section, and more especially since I have nothing novel to present. But there are so many and such great gaps in our knowledge of the essential nature and real causes of this many-sided affection that individual views, especially when based on experience, must always have more or less interest for those who are in daily contact with the many problems presented by this the most frequent of skin affections. As a measure of how much (or how little) we have learned in a century concerning the causes of eczema, it will be interesting to review briefly the various opinions which have been put forward by those who, with patient, earnest toil, laid deep and strong the foundations on which has been erected the splendid structure of modern dermatology, comparing them with those of the present day.

HISTORICAL CONSIDERATIONS.

Thomas Bateman in "A Practical Synopsis of Cutaneous Diseases," published in 1815, defines eczema as "a noncontagious eruption, generally the effect of irritation whether internally or externally applied, occasionally produced by a great variety of irritants in persons whose skin is constitutionally very irritable." Rayer, writing a few years later, described eczema as a noncontagious inflammation of the skin, and further stated that "our inability in a multitude of cases to discover any evident or even probable cause leads us forcibly to conclude that eczema is most generally evolved and kept up by hidden alterations of the fluids and solids"; but he made no attempt to define what these alterations were.

Devergie began the consideration of the causes of eczema by saying that "If one can not inherit an eczematous affection one may at least inherit the organization which favors its development," and he continued: "But eczema can spring from a host of different causes and it must be said that it is one of the maladies for which the predisposing cause, that which keeps *up and perpetuates* the cutaneous affection is most frequently unknown; . . . the determining causes are often readily found, but the *predisposing* causes are *determined* with difficulty. Not in ten cases in one hundred will the real cause of the affection be found sufficiently clearly indicated so that one may direct treatment against it."

If now we turn for a moment from the French school and return to England we find Erasmus Wilson, who so long deservedly occupied a commanding position in the field of dermatology, declaring: "The essential cause of eczema is debility, debility of constitution or general debility, and debility of tissue or local debility," the former presenting three forms, namely, assimilative, nutritive and nervous debility. He believed general debility by far the most frequent cause of this disease (278 out of 300 cases).

THE CONTRIBUTIONS OF HEBRA.

Among all those who have contributed to the building up of modern dermatology Ferdinand Hebra occupies easily the first place. Refusing to be bound by tradition and authority, with true scientific spirit always subordinating mere theory to observed facts, he greatly simplified the entire subject of eczema, doing away with the cumbersome and complicated classification of his predecessors, demonstrating "that certain affections of the skin hitherto described under different names must be regarded as only parts of one and the same disease, namely, eczema."

His conception, too, of the nature of this disease differed decidedly from those who had previously written about it. He regarded it as an inflammation of the skin which differed in no respect in essential features from inflammations of the same tissue arising from contact with irritants. For him the inflammation following the application of croton oil was just as much eczema as that which arose from some unknown or hypothetical cause. Heredity, which Hardy regarded as among the first of all the predisposing causes, in Hebra's opinion played no part in the production of eczema.

He considered faulty innervation as the most important element in its production. Under his teaching local treatment assumed a place of importance which it had never held before, and a large number of the nauseous decoctions of more than doubtful usefulness which had been prescribed from time immemorial for the expulsion of some theoretic *materies morbi*, "some peccant matter in the blood," were cast into the limbo of forgetfulness. Not that he denied the utility of internal treatment, but he clearly showed that in many instances local treatment was quite capable of bringing about a recovery to which internal remedies contributed nothing.

MORE RECENT STUDIES.

Let us now consider for a moment some of the views to be found in the most recent treatises. Crocker, while excluding from the category of eczema all inflammations of the skin due to strong irritants which act alike on the skins of all individuals, yet includes certain forms of dermatitis produced by substances which are irritants only to certain individuals. He regards an exhausted nervous system as one of the most common factors in the production of eczema, but "foremost among all internal disorders" he places derangement of the alimentary canal. Concerning the parasitic nature of eczema, which has recently come to occupy a prominent place, his views are as follows: "While a limited number of cases of local dermatitis indistinguishable from eczema are parasitic, in most the dermatitis, however caused, only opens the door to parasites whose presence keeps up the local irritation."

In 1890 Unna put forward the theory that eczema should be ranked among the parasitic diseases, the active etiologic agent being a micro-organism which he named the *morococcus*, and still more recently he has reiterated his belief that the clinical phenomena of eczema may be best explained and understood if we accept its purely external parasitic origin. This theory has been by no means generally accepted in its entirety, although a fair number of authors have accepted it in modified form. Le Redde and Hallopeau likewise regard it as a parasitic malady occurring in subjects especially predisposed.

Stelwagon assigns chief importance among constitutional causes to gout, rheumatism and "digestive debility." In speaking of external causes he remarks very suggestively: "There are cases of eczema which are persistent owing to the fact that the external exciting cause remains unknown or unsuspected."

Hyde and Montgomery find that "eczematous affections may occur in individuals who are in every respect superb examples of good health, and are associated with every variety of systemic disease whose effect on the cutaneous malady is quite unknown"; they, too, find that eczema is associated most frequently "with defects in digestion, assimilation and excretion."

These brief abstracts from standard French, German and American treatises on diseases of the skin may be taken as representing the prevailing views concerning the nature of eczema and its chief causes, local and general.

OPINIONS AS TO ETIOLOGY.

There is a pretty general agreement among authors that eczema may arise from purely local causes, but there is considerable difference of opinion as to whether all of these local inflammations should properly be included in the category of eczema. I believe, however, that the dermatitis which arises from repeated or long-continued contact of the skin with some irritant substance is just as much eczema as the local inflammations which arise from unknown causes. For example, the entire group of so-called trade eczemas, such as occur so frequently on the hands and forearms of those who work in dye stuffs and other irritant chemicals, and which often persist for an indefinite period, even after the patient is no longer exposed to the original cause, are surely eczema in every sense of the term. They are no less eczema because they arise from well-known causes.

Much stress has been laid by authors, almost without exception, on a special predisposition as a necessary prerequisite for the production of eczema by local irritants, but in what this predisposition consists, if it exists, we are entirely ignorant. It seems to me that eczema may occur in any individual if the local irritation is prolonged or sufficiently often repeated. Indeed, we have abundant evidence of this in many cases of the trade eczemas already alluded to in which the inflammation of the skin appears only after a shorter or longer period of immunity.

I recall the case of a distinguished teacher in one of our medical schools who, after having employed solutions of formaldehyd for several years for the preservation of his anatomic specimens without the slightest deleterious effect, began to suffer from a patchy vesicular eruption on the hands, presenting all the clinical features of eczema. His general health, which was always excellent, had undergone no perceptible alteration in the meantime. The skin having once become inflamed recurrences take place with ever increasing facility. In the case just quoted the patient had exposed his hands to the action of solutions of formaldehyd for two or more years without exciting inflammation, but when once a dermatitis had occurred the sensitiveness of his skin was so greatly increased that merely entering a room where a small quantity of formaldehyd vapor was present was sufficient to bring on a sharp attack of eczema. McCall Anderson has aptly remarked that the skin, like other portions of the economy, contracts bad habits, and having once contracted them often gives them up with great reluctance. As a matter of course the period of immunity varies greatly with the individual, one contracting an eczema very speedily, another only after repeated or prolonged exposures.

UNSUSPECTED CAUSES.

In many cases of local eczema, in which, owing to limitation of the eruption to exposed parts, or for other more or less obvious reasons, we are convinced of its external origin, it is frequently a matter of the utmost difficulty to detect the exciting cause owing to its often unsuspected nature. I have within the past two or three years seen two cases of eczema, both in women, situated on the sides of the face and neck, in which the eruption had been present for two or three winters, beginning with the appearance of cold weather and disappearing in the spring. In both cases there was nothing in the appearance of the disease to suggest that the inflammation was anything else than an erythemato-vesicular eczema of the ordinary type. There were patches of small vesicles seated on an erythematous base which were followed by oozing and crusting and accompanied by itching and burning. After observing the cases for some time it was discovered that the disease had in each instance appeared after the wearing of a new fur boa; with the abandonment of this particular piece of fur the disease disappeared permanently under simple local treatment. Cases like this are by no means the exception, indeed they are so common as to be within the experience of every one, and I am quite convinced that we should do well not to accept an internal cause for cases of localized eczema until we are able to absolutely exclude external causes.

While I am far from prepared to accept the theory of the parasitic origin of eczema, I am yet quite willing to accord to micro-organisms an important rôle in this disease. I think there can be no doubt that in many instances an acute dermatitis arising from some simple inflammation of the skin is transformed into a chronic eczema by secondary infection by some one of the many varieties of the micro-organisms which flourish so abundantly on the skin. Strong presumptive evidence in support of such a view is afforded by the fact that such local remedies as tar, ammoniated mercury, resorcin and other substances possessing more or less active parasiticide properties often are of great service in local eczemas.

INTERNAL CAUSES OF ECZEMA.

When we turn from the external causes of eczema to a consideration of its internal causes we immediately leave the well-beaten road of ascertained fact to enter a wilderness of speculation and hypothesis. It is not my purpose to enter into a detailed consideration of the internal causation of eczema, but it may not be without interest to examine briefly a few of the most generally accepted internal causes, belief in which seems frequently to have no better foundation than the shifting sands of theory, which in turn is based too often on insufficient or faulty observation. Among these, especially in infantile eczema, so-called dyspepsia, and digestive troubles of various kinds occupy the first place; but I think it may well be doubted whether these deserve this evil preëminence.

A half century ago Devergie observed that many patients with eczema were examples of perfect general health, and that frequently, if they had suffered previously from indigestion, they were free from it while they had their eczema. Unna never regulates the diet of infants with eczema since he has observed that in those cases accompanied by lowered nutrition, there is improvement in nutrition and consequent increase in weight as soon as the eczema has been healed by external remedies. A most illuminating paper in this connection is one published by Hall.[1] This observer in a series of cases of infantile eczema, some 60 in number, found that in most of them no disturbance of digestion preceded or accompanied the first appearance of the eruption, nor were there any symptoms of indigestion throughout the course of the disease. In most of the cases the patients were breast-fed and, therefore, not exposed to the indigestion arising from improper feeding, and only a small percentage of the cases occurred in the summer months, when, as is well known, infantile indigestion is most common. My own experience corresponds perfectly with that of Hall. Some of the worst cases of infantile eczema I have ever had under my care occurred in infants in whom it was impossible to detect any evidence of indigestion and who were perfect examples of vigorous, healthy babyhood.

There is a widely prevalent and deeply rooted notion that excrementitious matters circulating in the blood, especially those which pass out of the body by way of the kidneys, acting as irritants to the skin are frequent causes of eczema. If this notion were correct eczema should be a frequent complication of such diseases as chronic interstitial nephritis in which the output of waste through the kidneys is frequently reduced to its lowest expression and the blood in consequence is charged with an enormous amount of toxic substances which are often excreted vicariously through the skin to a greater or less extent. Under such circumstances the conditions should be especially favorable to the production of cutaneous inflammation; but eczema, instead of being a frequent complication of chronic nephritis, is quite infrequently associated with this affection. I have seen a considerable number of cases of nephritis and many cases of eczema, but I believe I do not exaggerate when I say that I can readily count on the fingers of both hands the instances in which I have seen these two diseases associated.

Rheumatism and gout figure largely in most lists of the internal causes of eczema, but I do not hesitate a moment to declare that in my opinion the former plays no part in the causation of this disease. As to gout, while I would not deny its influences as a causative factor, I believe its importance much exaggerated.

Now I would not be understood as denying that eczema may arise from causes within the body; on the contrary I believe that it does so arise in a considerable proportion of cases, but I must also confess I believe that a much larger proportion is due to external irritants. What I wish to emphasize is that our knowledge of the internal causes is extremely shadowy and ill-defined, seldom sufficiently accurate to afford a rational basis for internal treatment. All of us have seen patients with eczema get well many times under local treatment alone, but few of us, I venture to say, would expect very satisfactory results from internal treatment alone.

I am well aware that much of the foregoing must seem to many, if not most of you, as rankest heresy, but *"Hier steh' ich; ich kann nicht anders."*

Advance in knowledge comes only with conviction of ignorance; we shall never know anything worth while about the internal causes of this, the commonest disease of the skin, until we are honest with ourselves and admit the insufficiency of our knowledge; until we cease to repeat the meaningless generalities about internal causes with which our textbooks have been filled for a hundred years. *"En médecine plus qu'en toute autre science, il faut être vrai, il faut être consciencieux; c'est pour le médecin qui écrit le plus impérieux de tous les devoirs."*—Devergie.

ABSTRACT OF DISCUSSION.

Dr. Joseph Zeisler, Chicago: I do not entirely agree with Dr. Hartzell, but it has an exhilarating effect on me to find that an American dermatologist to-day stands on the ground occupied by me for many years under the influence of the teaching of Hebra and Kaposi. I have somewhat modified my views in regard to the nature and causes of eczema. Twenty years ago I would have been ready to subscribe to every word said here to-day, but since then my views have undergone a change, and I can no longer afford to look on eczema as a local matter entirely; nor would I feel that I had done my full duty, if called on to treat a child suffering from eczema, if I limited myself to external remedies, to the neglect of internal treatment and a proper investigation and regulation of the diet. I have come to look on rheumatism and gout as very frequent and important etiologic factors in eczema, and I regard the so-called nervous eczema as anything but local in character.

Dr. Grover W. Wende, Buffalo: I am fully in sympathy with Dr. Hartzell's views on the subject, and the method of treatment suggested by him.

Dr. William Thomas Corlett, Cleveland: In the main I agree with Dr. Hartzell, but, while I regard eczema as mainly a local disease, or, in other words, a condition of the skin which may be induced at times by local agencies, yet in infants gastrointestinal derangements frequently accompany the disease. It has also been my experience that the cutaneous disturbance will not yield satisfactory to local measures until the digestive tract has received attention. In most cases, aside from local measures, the selection of a suitable dietary, according to the age and other peculiarities of the child, is all that is required. So frequently has this association been encountered and so frequently has the latter observation been confirmed that I can but regard the internal disturbance as an etiologic factor in the causation of infantile eczema. That this is always the case I do not assert, as the delicate skin of the infant readily responds to local irritation. In treating eczema in general, while I do not go as far as Dr. Zeisler in the use of internal remedies—for I have seldom found them of benefit—I do believe that much may be accomplished in suitable cases by what is vaguely expressed as attention to the general health of the patient.

---

[1] British Jour. Dermatology, 1905, xvii.

Dr. Charles J. White, Boston: Although I have not made a particular study of eczema, I am inclined to agree with Dr. Zeisler rather than with Dr. Hartzell. The latter takes it for granted that, because we are ignorant of the internal causes of eczema, there can be none. On the other hand, he does find an external cause, and, therefore, assumes that all cases are due to external causes.

Dr. William A. Pusey, Chicago: I am in accord with Dr. Hartzell's views, as I understand them. In my opinion, we must start with the proposition that eczema is not a definite disease. It is not a pathologic entity. Eczema is simply dermatitis—a reaction in the skin produced by irritation of various sorts, which may be both local and constitutional or either. As a simple dermatitis it may be produced by many causes, but as soon as we discover a specific form of dermatitis, like scabies or seborrheic dermatitis, we eliminate it from the group of conditions that we call eczema. The typical form of eczema in children is, I believe, due in great part to internal causes. On the other hand, there are certain forms of eczema that are due to external causes. And the form due to internal causes presents no essential differences from the form due to external causes. For example, I recall, in a woman, a typical case of eczema of the hands of several years' duration of the form that we usually see produced by some metabolic disturbance. This patient had consulted several eminent dermatologists and she herself ultimately discovered that the eruption was due to contact with primroses, which she was accustomed to care for.

Dr. John A. Fordyce, New York: I agree in the main with Dr. Hartzell, whose views on this subject are somewhat similar to those expressed by me at the New Orleans meeting of this Section. The more I study eczema the more convinced I am that in the great majority of cases the causes of the disease are external. I teach my students that eczema is a reaction in the skin; that it is often impossible to differentiate the histologic features of a dermatitis produced by rhus or iodoform or by other chemical or mechanical irritants from a typical case of eczema in which we are unable to find the etiologic factor. We know that certain external agents will produce eczema. We theorize and say that certain internal causes may produce it, but we can not prove it. As a predisposing factor, we know that certain skins will respond to irritants, just as some mucous membranes are predisposed to catarrhal affections. My opinion is that eczema is a reaction generally produced by irritants from without in individuals with a skin that is predisposed. In exceptional cases the irritant may come from within.

Dr. Henry C. Baum, Syracuse: My first impression of eczema, obtained in Kaposi's clinic, was that it was a reaction of the skin due to external causes. I am convinced now that in any case of so-called eczema an external cause is operating, as Dr. Fordyce said, on a susceptible skin. This susceptibility is very frequently capable of demonstration as emanating from a constitutional cause. Take, for example, a case of infantile eczema in a breast-fed baby whose mother is constipated, nervous and run down. If we put the mother in a better state of health we can often cure the eczema without any treatment directed to the child. We know that some patients with eczema are made worse by an injudicious diet. Eczema may be due to both external and internal causes; otherwise we should have no explanation to offer for an external cause producing eczema in one individual and not in another. The classification and demonstration of the causes of eczema is not always as difficult as one might believe. For instance, I have observed many severe cases which were associated with indicanuria; the eczema disappeared promptly after the disappearance of the indicanuria. Hyperacidity is also frequently associated with eczema, and the alkalies are very useful as adjuvants in the treatment of such patients. If I were deprived of the advantages of constitutional treatment for my patients with eczema, I should feel much handicapped. I believe, as we all do, that the specific cause of eczema can oftentimes be demonstrated as external, but that in other cases it possesses constitutional features.

Dr. M. B. Hartzell, Philadelphia: I do not deny that eczemas may arise from internal causes, but I must repeat that I believe those of internal origin constitute a minority of the cases. The classification of these eruptions is somewhat after this fashion: If we know the irritant which produces the eruption, we call the latter a dermatitis; if we do not know it, we call it an eczema. We have not learned a single thing about the internal causes of eczema during the past century. Listen again to this quotation from Thomas Bateman. He defines eczema as "a non-contagious eruption, generally the effect of an irritant, whether externally or internally applied, but occasionally produced by a great variety of irritants in persons whose skin is constitutionally very irritable." This was written nearly one hundred years ago, and I do not think any one present to-day can improve on this definition. I have known of cases of eczema treated for a long time by a great variety of internal remedies, in which subsequently the eczema was shown to be due to an external irritant, precisely as in the case of primrose poisoning cited by Dr. Pusey. I still believe that most eczemas are of external origin, and that we know little about the internal causes.

RELATION OF PHARMACY TO MEDICINE.*

JOSEPH P. REMINGTON, Ph.M.
PHILADELPHIA.

The cordial relations existing between the two national bodies, the American Pharmaceutical Association and the American Medical Association, have been continued for many years, and in presenting this address, on behalf of the delegation, I am expected to review, briefly, the present situation of pharmacy in its relation to medicine.

Never before in the history of the two associations has the outlook been so promising, not only for the continuance of cooperation, but we are at last beginning to get results. The establishment of branches of the American Pharmaceutical Association in various cities and large centers has added greatly to the influence and usefulness of the parent body.

What is known as the "propaganda" for circulating information among the medical and pharmaceutical professions about the U. S. Pharmacopeia and National Formulary preparations has spread during the last year, notwithstanding the opposition of those interested in proprietary and special preparations, who predicted the failure of the "propaganda." The work is going on; it is essentially a work of education. Commercialism, in its various forms, good and bad, has dominated therapeutics, and while I do not join in the hue and cry against manufacturers of specialties (for this is a legitimate business), I do take issue with the medical profession for allowing itself, with a few exceptions, to depend on the specialty men for their knowledge of therapeutics. The members of this section have often heard statements of this kind, and it seems like an old story; but it is only through constant repetition and a firm adherence to the principles, so often enunciated, that progress is being made.

Patient and persevering effort, all along the line throughout the country, is bringing results. The old method of attacking the sins and the sinners in both professions has proved a failure, and it always will. The church and the state have suffered, and progress has been impeded by pessimism and the efforts of those whose pecuniary interests are affected and who have motives for excusing or defending what they believe to be their interests by attacking the earnest efforts of disinterested men who believe in the highest ethical ideals to elevate both professions and who stand for the greatest benefit to the greatest number. How often men refuse to go to church, saying "There is a man who goes to church every week, but I am a better man than he is." And so in the affairs of state, "There is a man who is mayor or governor, and everybody knows he is unfit, I wouldn't do what he does for any amount of money." Such men sit down and drop their hands idly, satisfying any twinges of conscience by wrapping themselves up in a mantle of self-righteousness. Is it not better to accept, in our time and generation, our fellow-men as they are, and patiently and persistently, but kindly, set before them a more excellent way?

---

* Read as delegate from the American Pharmaceutical Association to the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

This is now the policy which pervades the earnest efforts to increase the influence of the "propaganda." Let us admit freely, that in both professions there are individual members who are unworthy, but why dwell on the sins and sinners; why not set before them a way of escape? Condemnation, even if it is just, is worthless, unless something better is put in the hands of the ignorant or careless; indeed, it is a most difficult task, at present, to arouse the interest of good men in both professions, in some quarters. The first principles of ethics must be explained, and even when these are accepted with enthusiasm the convert must be bombarded with literature and often personal effort to keep him long enough in the new way until he can see the results, which come from the use of definite preparations, fully up to the pharmacopeial standards.

In the pharmaceutical ranks there is also much work to be done. Physicians complain that there is yet ignorance, on the part of the pharmacist, about preparations of the Pharmacopeia and National Formulary, and that they can not get, promptly, what they order or prescribe. While this is natural, under the circumstances, it is to be deprecated, and there is no excuse to offer, but it is a condition which is being rapidly remedied. The work of the American Medical Association, in providing a manual of Pharmacopeial and National Formulary preparations in a convenient form for consultation, has been a wise step in educating physicians. If every physician in the country would promise to use such of these preparations as he can, without at once forsaking entirely the specialties that he has been using, the most practical beginning will have been made; common sense would plainly indicate such a course. And again, as we are starting to revive prescription-writing at its best, the old relation, which has been largely abandoned of late years, of the physician calling on the pharmacist in his neighborhood and asking to be shown the newer preparations which are ethical, must lead to more useful results than the prescribing of a ready-made remedy, which probably has been tried already by the patient, with unsuccessful results.

In conclusion, the American Pharmaceutical Association presents to this body its greetings, and offers to coöperate with the American Medical Association and this section in every effort to advance ethical pharmacy and rational therapeutics; and, in this way, it is believed that the tide of "therapeutic nihilism," which is fast waning, will have been turned backward, and the medical profession, while keenly alive to every improvement in the armamentarium, will soon be placed on a solid foundation of truth.

OPHTHALMOLOGY FOR GENERAL PRACTITIONERS.*

LEARTUS CONNOR, A.M., M.D.
DETROIT.

DEFINITION.

General practice does something for every class of cases; special practice everything for a single class. General practice ophthalmology should harmonize with other college courses and meet the needs of the family physician; special ophthalmology supplements college courses and family practice. General practice is a large load drawn slowly by many horses; special practice a light load drawn swiftly by a single horse. General practice is extensive farming; special, intensive. For convenience of discussion we shall call "the ophthalmology for students of general practice" "general practice ophthalmology," as contrasted with "special ophthalmology."

STANDPOINTS OF STUDY.

"General practice ophthalmology" may be studied from many standpoints: Its relation to other college courses; to other kinds of family practice; to the entire field of medicine; the needs of the laity; and to special ophthalmology.

1. *Relations of General Practice Ophthalmology to Other College Courses.*—Respecting these courses, it is to be noted that the last half century has projected into medicine many radical discoveries and revolutionary inventions along fundamental lines. Instruments of precision, laboratory work, antiseptic methods, new sera, have introduced a possible exactness before undreamed of. Prior to this epoch one teacher was responsible for an entire course; so the mastery of his lectures was the mastery of his course. Such mastery equipped the young practitioner for his life work, giving definite ideas on which to begin the management of his first cases—ideas that were the result of his teacher's long study and active practice, and so worthy of confidence. With increased material and the introduction of laboratory and clinical methods, many teachers were needed in each course. The results were easy to see, as "too many cooks spoil the broth." Confused by conflicting instructions, on meeting his first serious case the young doctor often hesitates, and another is substituted.

The number, length and quality of college courses vary; in Cornell there are twelve general and thirteen special courses, ophthalmology getting ten lectures and twelve hours of section work, being classed as a minor subject. Doubtless Cornell, with other leading colleges, is struggling to so proportion and harmonize these twenty-five courses that they shall afford the student the best chance to become a first-class family physician.

A study of all American medical college announcements as related to their "ophthalmology for students of general practice" showed:

1. An utter lack of uniform requirement in hours of study, subjects studied or amounts of such study, in clinics, recitations or demonstrations.
2. Such a mixture of general practice ophthalmology with special as is confusing to both general and special students.
3. Not one institution made clear what the student must know and be able to do. Surely the student of

---

*Read before the American Academy of Ophthalmology and Oto-Laryngology.

"general practice ophthalmology" has our sympathy in his endeavor to learn from college announcements the nature and extent of the job before him. The situation is the more distracting, as like conditions exist in each of the twenty-five or more courses. Since each course is a selection from a vast pile of settled facts, it is fair to expect the selector to give the student a list of the subjects selected, with the amount of each.

A short time ago, at the meeting of a Michigan county medical society, a poll was taken of the members relative to the instruction they had received in ophthalmology. Not one had heard a lecture on refraction, much less been taught to refract; all had seen plenty of eye operations (but none had ever operated); a few of their eye cases went to the special ophthalmologist, but most to the opticians. In all large towns opticians practice ophthalmology; in the country traveling opticians live on neglected cases of refraction. Over the same area are cases of blindness from eye infections which family physicians failed to treat wisely. Surely, something must be defective in the training of family physicians, that so generally they are unqualified to occupy this neglected field of medicine.

Evidently the time and energies of the average medical student are fully occupied with existing courses, so that if he is to be better trained in general practice ophthalmology a new deal must be made. What shall this be? Time forbids an answer now, but we may inquire:

1. Is the time allotted each college course such as to produce the best family physician?
2. How much of each course is inaccurate, misleading, untrue or simple padding?
3. What part of the course on ophthalmology has any fitness for the working needs of the *family physician?*

I have a strong conviction that were all college courses free from chaff and full of good wheat, there would be plenty of time and energy for a general practice ophthalmology adequate to enable the family physician to treat cases neglected or now in the hands of the opticians.

An important factor in the working value of a medical course is the teacher. If he has learned the art of teaching as well as the art of medicine, he can so systematize his subject and stimulate the student that far more can be accomplished within a given period. That a doctor should acquire the art of teaching by practicing on students is quite as bad as a layman learning the art of medicine by practicing on the sick. General practice ophthalmology needs men trained both in medicine and pedagogy to furnish students the best college course and give family doctors a fair show in actual practice.

2. *The Relations of General Practice Ophthalmology to Other Kinds of Family Practice.*—The family physician does team work; side by side with ophthalmology are dermatology, obstetrics, gynecology, laryngology and other classes of practice—all limited, as is ophthalmology. He finds that his ophthalmology helps his internal medicine, his neurology, his obstetrics and every other class of cases; in return, every class of cases helps his ophthalmology. He comes to realize, as a simple specialist can not, the helpfulness of one class of practice to another, and to *all combined.* Thus, the student's failure to master general practice ophthalmology mars the harmony of his education and unbalances his practice, as does the lack of one horse from a team cripple its power.

3. *The Relations of General Practice Ophthalmology to the Entire Field of Medicine.*—Already we have noted the fact that because the family physician lacked adequate equipment in ophthalmology, vast amounts of medical practice have been neglected by the profession and picked up by laymen, termed opticians; and many eyes are lost from unchecked infectious eye diseases. In these and allied ways general medicine has been discredited and impoverished, the family physician lost much in fees, prestige and mental quality.

4. *The Relations of General Practice to the Needs of the Laity.*—The laity need doctors when their eyes are disabled, and should be taught such habits as will restrict their disabilities to a minimum. In towns the "well to do" can secure the services of special ophthalmologists; the very poor seek relief at hospitals and dispensaries. Between these two extremes is a large class unwilling or unable to pay the special ophthalmologist and without the dispensary habit. This class is a large patron of opticians, though these persons have family physicians who ought to have trained them better. (Alas, the family physicians never were taught the situation, and so, too often, are allies of the optician, instead of their own specialists.)

For this grave situation (from a professional standpoint) the only remedy is a qualification of every family physician in general practice ophthalmology. In regions distant from towns conditions demand of the family physician an ability to care for all minor eye troubles and an obligation to place the major ones in the hands of a special ophthalmologist. The laity needs an all-round doctor all the time, a specialist occasionally.

5. The relations of "general practice ophthalmology" to "special" will prove satisfactory only when both parties have a general practice ophthalmology through which they may cooperate. This common knowledge will enable the family physician to detect ocular disabilities now unrecognized, treat the simpler and refer the rest to a specialist, with a promptness essential to the best results. As this custom prevails, eye practice now in the hands of opticians or neglected will come under the control of competent physicians. The specialist should render positive aid and encouragement to the family physician as he seeks to cultivate this unoccupied field.

The principles inherent in a general practice ophthalmology may be stated thus: (1) The several college courses should be proportioned on the basis of their value in making the best family physician, a task for college faculties, or, in their failure, for state licensing boards. (2) The materials for each course, didactic, clinical, demonstrative or laboratory, should be selected by the same standard. (3) Each course should be outlined with unmistakable exactness, so that the student may know definitely, at the beginning, what he must master, and how much. (4) As abundant *facts* exist to occupy every course: *all* else should be excluded, leaving all wheat but no chaff. (5) No teacher should advocate methods of practice, the use of remedies or operations unproved by his own experience as the best known. (6) So far as possible, *students* should have experience in each mode of practice, make the examination, direct the treatment, and (under the teacher) be responsible for the results. College courses conducted along these lines would enable the student of general practice ophthalmology to perform an amount of high grade work paralyzing to his neighbor trained in a haphazard manner.

The subjects of a general practice ophthalmology will vary with the selector's training. That I might have the judgment of professional leaders, I mailed a circular letter to about a hundred special ophthalmologists, surgeons, professors of practice of medicine, neurologists and family physicians, asking two questions: (1) What, if any, knowledge of ophthalmology is essential for the best equipment of a general practitioner? (2) What classes of eye cases should he be prepared to treat? (For the prompt and courteous answers to these queries I cordially return thanks.) The replies may be grouped as follows:

A. Those who thought no general practitioner should treat an eye case, but send every one to a specialist.

B. Those who believe the family physician should be able to practice special ophthalmology and special everything else, do all eye operations, as well as operations in gynecology and general surgery.

C. The neurologists were strong on those points at which ophthalmology touched their work, holding that to those should be added an ability to manage eye infections, including iritis and differentiate glaucoma from iritis, etc.

D. Many believed the family physician should treat infectious eye diseases, diseases of the uveal tract, and make a correct diagnosis of optic neuritis.

E. Few believed the family physician should be able to recognize and treat cases of simple presbyopia, myopia and hyperopia.

With much hesitation I venture the following outline of the subjects I would group in general practice ophthalmology:

1. It would not include operations within the eyeball, or on the eye muscles, the treatment of muscular unbalance, or complicated cases of refraction.

2. It should qualify students to recognize and treat injuries of the eye, except foreign bodies within the eyeball, all infections of the eye, diseases of the uveal tract and simple presbyopia, simple myopia and simple hyperopia.

3. It would enable students to make a simple inspection of the eyes; to note the movement of the lids and eyeballs; the size of the pupils, absolute and relative, their motility and changes with intensity of light; the color of the iris, etc.; to take the visual fields roughly with fingers or blackboard, noting their size, shape and similarity in the two eyes; to note the tension of the eyeballs as compared with the tension of a known healthy eye; to have practice in everting the lids, and to be familiar with the appearance of the conjunctiva and adnexa.

4. It would practice students in simple refraction until they were familiar with methods and reasonably sure of their results. It would familiarize them with convex and concave glasses, both in the trial case and as sold in the shops, and the adjustment of frames to different faces. General practice ophthalmology would enable the student to differentiate the several forms of conjunctivitis; the varieties of iritis in their different stages; the several lid disorders; redness of the conjunctiva from a foreign body, from a conjunctivitis, keratitis or iritis; a dacryocystitis from either a chalazia or hordeolum when situated near the inner canthus; a corneal opacity from cataract; glaucoma from iritis, conjunctivitis or corneal ulcer.

In treatment, general practice ophthalmology will utilize laboratory findings in doubtful cases of infectious eye disease and apply the agents known to destroy the infection, such as silver salts in gonococcus infection, zinc sulphate in infection with the diplobacillus of Morax-Axenfeld; mercury ointments in blepharitis, plus correction of refraction defects; tincture of iodin in corneal ulcers; expression and antiseptics in trachoma; atropin with mercury or salicylates internally in iritis; eserin in glaucoma (till the case can reach a specialist); hot water locally in most cases of acute inflammatory disease and malnutrition. The family physician's knowledge of intestinal disorders will prove helpful in all these cases.

General practice ophthalmology will teach the student the use of the convex lens for oblique illumination; use of the foreign body spud; of the knife and scoop for the removal of chalazia; the use of the ophthalmoscope to recognize a normal fundus. It will teach the nature and effects of atropin, hematropin, euophthalmin, eserin, cocain, eucain, dionin, boric acid, yellow oxid of mercury ointment the silver salts, zinc sulphate, copper sulphate and hot water.

Assuming that "general practice ophthalmology" is necessary for the best interests of the profession, the people and the art of medicine, how may it be secured with least friction at the earliest date?

1. We need the widest publicity of existing conditions and an exhaustive study of the means for their betterment.

2. We must enlist the several state organizations in the education of family physicians for their enlarged sphere—the care of all the disabled. The Michigan State Medical Society has directed its council to take the matter up with the county societies and the State Board of Registration.

CONCLUSIONS.

1. General practice ophthalmology is all of ophthalmology the student can master without violence to other courses, and a family physician can practice in harmony with his work.

2. It includes four factors—the ability to recognize and treat eye injuries (except foreign bodies within the eyeball); the recognition and treatment of all eye infections and diseases of the uveal tract; the recognition and management of simple presbyopia, simple myopia and simple hyperopia.

3. The best interests of the profession and laity demand a mastery of general practice ophthalmology by every physician.

4. The medical college obstacles to this can be removed (1) by eliminating from every course all chaff; (2) by adjusting the proportion of courses to the actual needs of the family physician, and (3) by insisting that all the professors be trained in the art of pedagogy, as well as the art of medicine.

5. The machinery of state medical societies and the American Medical Association should be used to awaken the interest of licensed physicians and induce registration boards and medical colleges to place among their requirements a "general practice ophthalmology."

91 Lafayette Boulevard.

Hernia of the Appendix.—W. B. DeGarmo, in the *Post-Graduate*, August, 1908, states that in hernia patients it is important to remember the possibility of the appendix being in the hernial sac instead of assuming that all the patient's discomfort is due to the hernia.

THE OCULAR REACTION TO TUBERCULIN.

WITH REPORT OF 202 CASES.

OSCAR H. WILSON, M.D.
Assistant Demonstrator Clinical Medicine, Jefferson Medical College; Assistant Registrar, Philadelphia General Hospital.
PHILADELPHIA.

The necessity for the early recognition of tuberculosis was never more apparent than it is to-day. The difficulties attending the recognition of this affection in its incipiency are numerous, this being especially true of obscure lesions of the lymphatic glands, bones, joints, viscera and nervous system. Infection of these structures with the tubercle bacillus *frequently* gives rise to indefinite and ill-defined symptoms and signs which often leave us in great doubt as to the nature of the underlying pathologic process. With the introduction of refined methods of diagnosis we are able to arrive at earlier and more definite conclusions. The employment of tuberculin subcutaneously proved to be a valuable addition to our diagnostic armamentarium, but this use of tuberculin subcutaneously is attended with numerous objections and dangers which are too well known to require repetition at this time.

The simultaneous introduction of the ophthalmic test by Calmette[1] of Lille, France, and Wolf-Eisner[2] of Berlin gives promise of being a simpler and more accurate method of administering tuberculin for diagnostic purposes. The reports of recent investigators seem to confirm in general the claims made by the originators of this test. Too little work has yet been done to establish the exact status, limitations and dangers of the test. In the endeavor to add something to the sum total of our knowledge of this subject I applied this test to 202 hospital patients. The majority of patients selected were those presenting definite symptoms and signs of tuberculosis, so that the test could be compared with the clinical and bacteriologic findings.

CLINICAL OBSERVATIONS.

The results of my observations are as follows:

Condition.	Cases, No.	Positive.	Negative.
1. Pulmonary tuberculosis	120	106	14
2. Pulmonary tuberculosis (doubtful)	13	3	10
3. Apparently healthy persons	53	3	50
4. Enteric fever	11	6	5
5. Syphilis	5	0	5

It will be noted that fourteen cases of undoubted tuberculosis yielded a negative result. In six of these cases the pulmonary lesion was well healed and inactive. Of the remaining eight patients, three were moribund and two were suffering with acute miliary tuberculosis. Tuberculin in amounts varying from 1/1000 to 1 milligram was injected subcutaneously in the fourteen cases which yielded a negative result. In four cases it caused the development of the characteristic reaction in the eye, which had been subjected to the tuberculin instillation. The moribund patient and those with acute miliary tuberculosis failed to respond. In five of the cases which gave a positive reaction the employment of tuberculin subcutaneously seemed to aggravate the existing inflammation, but in none did it cause a reappearance of the inflammatory signs after they had abated.

It will be noted that in three of the doubtful cases there was a positive reaction, likewise in three apparently healthy individuals. These patients were subjected to a most searching examination, but in none could the presence of tuberculosis be detected.

Twenty-five of the apparently healthy individuals who gave a negative reaction were subjected to a second instillation in the same eye, and in eighteen there was a positive result. Some of the most severe reactions observed were obtained in this class of patients by a second instillation in the same eye. The cases which yielded a positive result were subjected to a third instillation in the other eye, with a negative result in each case. This experiment seems to prove that the state of anaphylaxis is not transferred to the other eye.

Five patients in whom the state of anaphylaxis was established by two instillations in the same eye were given 1/100 mg. of tuberculin subcutaneously. No constitutional symptoms followed, showing an absence of general hypersusceptibility.

Tuberculin, in amounts varying from 1/1000 mg. to 1 mg. was injected subcutaneously in fifteen of the healthy patients who gave a negative reaction. In none did it cause the development of the characteristic conjunctival inflammation.

Five of the six patients with enteric fever who gave a positive reaction were at an early period of convalescence; one was obtained during the active stage of the disease. Of the five patients who yielded a negative result, four received instillations during the third week of the disease, the remaining one during convalescence.

Regarding the occurrence of a positive reaction in typhoid, Calmette[3] suggests that "there may be some connection between the presence of a few tubercle bacilli in the mesenteric glands and the typhoid infection of these glands and thence of the entire organism by the typhoid bacillus, which is a normal inhabitant of the intestines in a number of healthy persons."

Cohn[4] believes that a specific hypersusceptibility to bacterial albumin in general is evolved in the course of typhoid fever, as well as to typhoid bacillus extracts in particular. Whatever may be the true explanation, the fact that a certain proportion of all typhoid patients react is well established.

The syphilitic patients, all of whom failed to react, were given instillations in the endeavor to determine if the other chronic infectious granulomata also responded to instillation of tuberculin. No cases of leprosy, actinomycosis or glanders being available, the occurrence of the reaction in these affections could not be determined.

PREPARATION EMPLOYED.

The tuberculin tablets which are so frequently employed are directed to be dissolved in sterile water; solution, however, can not be effected, the resulting preparation containing suspended insoluble particles, which gradually settle to the bottom. Care must be exercised to mix thoroughly before using, so as to be assured a uniform product. The suspended insoluble particles, in my opinion, are capable of exciting considerable irritation in susceptible conjunctiva. In this way pseudoreactions may be produced. Calmette believes that the presence of glycerin or carbolic acid in the new or old tuberculin is sufficiently irritating to produce pseudoreactions. MacLennan[5] apparently disproves this statement, as he instilled into many healthy eyes 1 per cent. solutions of glycerin and carbolic acid without producing a reaction.

[4] Berl. klin. Wchnschr., xliv, 1499-153.
[5] Brit. Med. Jour., Dec. 7, 1907.

I believe that as yet there is no definite method for standardizing tuberculin; therefore, we can not be assured of always employing a uniform and definite product.

Smithies and Walker,[6] in a recent paper, stated that the tuberculin they employed was a suspension of fragments of dead bacilli. I have examined several tuberculin preparations on the market and in none was I able to demonstrate the presence of bacilli or fragments of such. In my experiments I employed tuberculin solutions (?) of 0.5 and 1 per cent. The 0.5 per cent. solution gave the most satisfactory results and should be employed in nearly all cases. By so doing the possibility of securing violent reactions is reduced to a minimum. Normal salt solution was frequently employed to dissolve (?) the tuberculin. It is admirably adapted for this purpose and seems to be much less irritating than sterile water.

THE REACTION.

There seems to be a difference of opinion existing as to what constitutes a reaction. Calmette in his original contribution to this subject described the reaction as "a slight swelling and redness localized principally about the caruncle, the inner canthus and the conjunctiva." Auberet and Lafond[7] and Auberet and Magne[8] describe four degrees of reaction, depending on the severity of the inflammation. Their classification is cumbersome and serves no useful purpose. For recording reactions I employed the schema devised by Baldwin[9] and found it simple and convenient. His plan is as follows:

Negative.—No difference in color when lower lids are pulled down and compared.
Doubtful.—Slight difference with redness of caruncle.
+ = Distinct palpebral redness with secretion.
+ + = Ocular and palpebral redness with secretion well marked.
+ + + = Deep injection of entire conjunctiva, with edema of lids, photophobia and secretion.

In the series of patients examined the average time of development of the reaction was about five hours. The earliest made its appearance in two and one-half hours; in two the reaction was delayed for nearly twenty-four hours. These so-called delayed reactions have been described by other writers. They may be due to faulty technic or to the fact that the instillations were made in the negative phase so that a response did not occur until the positive phase was established.

Several fleeting reactions were observed, in which very mild inflammatory signs appeared and disappeared in the course of twenty-four hours. These may be attributed to faulty technic, some of the tuberculin escaping, or to the patient deliberately removing the tuberculin from the eye. I am inclined to think that they are pseudoreactions, as most occurred in individuals free from tuberculosis.

The marked inflammatory signs in most cases abated in forty-eight hours, but in a few cases they persisted for seventy-two hours. The vascular engorgement, however, was distinctly visible in many cases one week after the instillations. Several violent reactions were observed, but these, I believe, can be avoided in most cases by employing tuberculin of proper strength.

The lack of uniform and definite standards for judging the occurrence of the reaction in all probability will account for some of the varying results of numerous observers. Recent writers on this subject seem to be of the opinion that the intensity of the reaction bears no relation to the extent of the disease. While this may be true in a general way, yet my experience shows that those individuals with small lesions and good resisting powers gave the most prompt and pronounced reactions.

The claim of Wolff-Eisner and Teichmann[10] that the intensity of the reaction has an important bearing on the prognosis seems to be confirmed by my observations. Those patients who were waging vigorous warfare against the invaders and apparently successfully combating the disease, always gave a prompt and vigorous reaction; while in those who were overwhelmed with the infection the reaction was slight or *nil.*

CONTRAINDICATIONS AND DANGERS.

Blepharitis, conjunctivitis, keratitis, trachoma, and iritis are all said to contraindicate the employment of this test. Eyestrain from errors of refraction need not prevent the application of the test. In the series of cases examined were several elderly individuals with a chronic hyperemic condition of the conjunctiva. The instillations served to aggravate the pre-existing inflammation in those patients who were tuberculous; no effect was apparent in non-tuberculous patients. Numerous reports of untoward effects following the instillation of tuberculin have appeared in the literature. Chief among these is catarrhal ulceration of the cornea, which ophthalmologists claim is often not apparent to an untrained observer. In the comparatively large number of patients whom I examined some severe reactions were observed, but in no instance did serious results follow the instillations.

TREATMENT OF THE CONJUNCTIVITIS.

The inflammation was rarely severe enough to demand active treatment. In the great majority of cases no treatment at all was instituted. In the more severe cases cold compresses were applied to the lids and the conjunctival sac cleansed frequently with a warm solution of boric acid. Solution of adrenalin chlorid (1 to 10,000) was employed in a few cases. These measures relieved the subjective symptoms, but apparently did not diminish materially the intensity or duration of the reaction.

TUBERCULOUS CASES WHICH FAIL TO REACT.

It has been the experience of numerous observers that cachectic, moribund and very advanced paients fail to react. This is also true of acute miliary tuberculosis and of cases in which the lesion is well healed and inactive. My experiments confirm in every particular the results of these investigators. It seems unreasonable to expect reactions to occur in advanced cases, any more than we could hope to obtain a response to the hypodermic administration of strychnin or other alkaloid. Fortunately in this class of cases the diagnosis is rarely in doubt. The difficulty frequently attending the recognition of miliary tuberculosis is well known, and it was hoped that the ophthlamic test would prove a valuable aid in the diagnosis of this affection. Experience, however, has proved the test to be of little value in this condition.

The two patients whom I examined gave a negative result. The subsequent administration of tuberculin subcutaneously failed to develop the reaction.

[6] THE JOURNAL A. M. A., Jan. 25, 1908, l, 259.
[7] Gaz. hebd. d. sc. méd. de Bordeaux, Aug. 4, 1907.
[8] Jour. de méd. de Bordeaux, Aug. 25, 1907, xlix, 1969
[9] THE JOURNAL A. M. A., Dec. 14, 1907.
[10] Berl. klin. Wchnschr., xlv, 45-88.

The cause for the failure of the reaction in this class of patients has not yet been satisfactorily explained. Smithies and Walker[11] believe that the blood is so laden with tubercle bacilli that they seize the available lysins and opsonins, leaving little or none to combine with the bacilli, or the fragments of such enmeshed in the conjunctiva. As a consequence, the endotoxin is not released locally and no inflammation ensues. Their theory, however, is based on the erroneous idea that the tuberculin consists of fragments of dead bacilli.

The failure to obtain the reaction in a certain proportion of cases, in which the lesions are well healed and inactive, probably finds its best explanation in the fact that sufficient tuberculin is not being elaborated into the circulation to bring about a sensitization of the conjunctivæ.

There are cases of undoubted tuberculosis which fail to react, and this failure may be dependent on one or several of the following factors:

1. *Faulty Technic.*—I have seen several cases in which the negative results could be directly attributed to this cause.

2. *Poor Tuberculin.*—The possibility of the tuberculin being inert must always be borne in mind. The tuberculin of a well-known manufacturer, in my hands, gave a negative result in twenty-five undoubted cases of tuberculosis. The same patients gave a prompt response to another preparation of tuberculin, care being exercised to make the second instillation in the opposite eye.

3. *Instillations Made in the Negative Phase.*—This question has not yet been definitely settled, but it is possible that future experiments will prove that tuberculous patients will only react when in the positive phase, that is, with the opsonic index normal or above, and with the defensive forces of the body active.

4. *Method of Infection.*—Raw advanced the view that certain forms of tuberculosis were due to infection with human bacilli, while others were due to infection with bovine bacilli. This suggests the possibility that failure to obtain reaction in certain tuberculous patients may be due to the employment of tuberculin prepared from a different type of bacillus from that with which the patient is infected.

REACTION IN APPARENTLY HEALTHY PERSONS.

My experiments, as well as those of other investigators, show that a certain number of apparently healthy individuals give a positive reaction. The occurrence of reactions in these cases may be dependent on one or more of the following factors:

1. The great difficulty in demonstrating certain patients to be clinically tuberculous. This is well illustrated by the autopsy records; which show a large number of cases to be tuberculous, in which the condition was not apparent during life.

2. The tolerance of the conjunctiva of healthy persons to tuberculin. Tuberculin solutions of 1 per cent. or above are capable of exciting inflammation of the conjunctivæ of healthy persons. Solutions of this strength should rarely be employed.

3. The possibility of the patient rubbing and irritating the eye, thereby producing a pseudo reaction, must always be borne in mind.

4. Idiosyncrasy. It is possible that experience will show that certain individuals possess a marked susceptibility to tuberculin, as is frequently manifested to certain drugs.

CONCLUSIONS.

1. A positive reaction is fairly reliable evidence of the existence of tuberculosis.

2. A negative result does not exclude the possible presence of tuberculosis.

3. In properly selected cases and with tuberculin of proper strength, the test is free from any serious danger.

4. Tuberculin solutions of 0.5 per cent. are to be preferred in all cases; solutions of greater strength should rarely, if ever, be employed.

5. The test is of value from the standpoint of prognosis. A prompt and vigorous reaction indicating that the patient is successfully combating the disease.

6. Very advanced and moribund cases fail to react, also cases of miliary tuberculosis.

7. The administration of tuberculin in moderate amounts, subcutaneously, will not develop the reaction in healthy persons. In tuberculous patients it accentuates the pre-existing inflammation, and may cause the appearance of the reaction. It apparently fails to develop the reaction in cases of acute miliary tuberculosis

8. The theory of the existence of the state of anaphylaxis or local hypersusceptibility best explains the occurrence of the reaction.

9. No more than two instillations should be made, the opposite eye being employed for the second test.

10. The state of anaphylaxis or local hypersusceptibility produced in healthy persons is apparently not transferred to the opposite eye.

11. The sensitization in the eye does not seem to be followed by a general hypersusceptibility, manifested by a reaction to the subcutaneous injection of tuberculin.

12. In the great majority of cases no constitutional symptoms are associated with the reaction. No alteration occurs in the physical signs, such as frequently occurs following the administration of tuberculin subcutaneously.

13. A certain proportion of enteric fever cases give a positive reaction. This is most apt to occur in patients who are convalescing.

14. As yet there is no definite evidence for regarding it as a group reaction.

15. When the lesion is well healed and inactive a negative result is often obtained.

16. The test should not be resorted to if the diagnosis can be made by physical signs and symptoms.

The investigations which form the basis of this paper were conducted in the wards of Dr. Hobart A. Hare, Dr. S. Solis-Cohen and Dr. H. R. M. Landis, in the Jefferson and Philadelphia General hospitals. Without their aid the completion of this work would have been impossible. I feel deeply indebted to them for allowing the tests to be conducted in their wards.

5128 Spruce Street.

Treatment of Hammer Toe.—E. Martin gives an illustration in the *Zeitschrift für Ærztliche Fortbildung*, Oct. 1, 1908, of a simple method with which he keeps hammer toe under control. He passes a piece of elastic webbing, about an inch wide and a yard long, over the affected toe and under the other toes, then crosses the ends of the elastic over the dorsum of the foot and behind the ankle, fastening the ends together in front above. If the toe is contracted downward the elastic band is passed under it and over the other toes. This simple measure has cured many cases of contracture in his experience and aided in the healing after tenotomy.

ABNORMAL SECRETION FROM THE MAMMARY GLANDS IN NON-PREGNANT WOMEN.*

GEORGE GELLHORN, M.D.
Lecturer on Gynecology, Medical Department, Washington University.
ST. LOUIS.

An accidental accumulation of cases of abnormal secretion from the mammary glands in non-pregnant women, coming under my observation, led me to investigate the literature on this curious phenomenon.

The occasional occurrence of such an abnormal secretion in the newborn of either sex is sufficiently known, but a satisfactory explanation has not yet been given. Steifensand,[1] in 1845, was the first to call attention to the fact that, in the newborn, all glands exhibit a very pronounced activity. Basch[2] ascribes the phenomenon to the welling up of the secretion toward the surface, thereby loosening the hornified epithelium which clogs the orifices of the milk ducts. Bumm[3] says that the skin of the newborn is very sensitive and responds to the influence of air and light by reddening and exfoliation of the uppermost layers of the epidermis. This irritation of the skin is also the cause of the secretion of the mammæ which, as yet undeveloped, have the appearance of somewhat large sweat glands and secrete, within the first week, a few drops of a whitish fluid. On the other hand, Longridge,[4] who carefully studied the mammary glands of stillborn infants, finds that in large children with abundance of subcutaneous fat the breasts are usually well developed irrespective of sex. The breast tissue can be distinctly felt as a solid mass lying below the primary areola, and on squeezing it a fluid which, on microscopic examination, is indistinguishable from milk, can be expressed. Starling and Lane-Claypon,[5] pursuing the idea that chemical factors must play an important rôle in the correlation of function between different parts of the body, think that the activity of the infantile breast is brought about by the presence in the fetal circulation of the same body which acts as the physiologic stimulus to the mother's breasts; this body probably originates within the fetus itself. The existence of such a "chemical messenger" is also assumed by Halban, though his theory of its nature and origin materially differs from that of Starling. Halban concluded from his researches[6] that pregnancy produces local phenomena in the fetus which are identical, though not as intense, with those in the organism of the mother. Thus, not only the uterus, but also the mamma of the fetus hypertrophies in pregnancy and exhibits characteristic histologic changes. In a later study[7] he attributes the causation of this mammary hypertrophy to an internal secretion of the placenta.

Whatever the nature of this "witches' milk" of the newborn may be, the activity of the breast soon ceases or lies dormant until the mysterious force of puberty stimulates it into new life. The swelling and soreness of the virginal breast, together with a limited secretion of a colostrum-like fluid on the advent of the first menstruation, are too frequent an occurrence to require more than mention. In some cases this correlation of mammary and uterine functions becomes permanent, at least for a number of years. Only the remarkable case reported by Blum[8] may be here recorded. A girl, 17 years of age, with two well-developed mammæ in their normal place, has, in the region of the mons veneris, a third mamma of the size of a goose egg, with seven nipples. Of these only four secrete regularly a copious amount of colostrum before and during the first day of menstruation. The two normal mammæ do not secrete at all.

In exceptional instances this lacteal secretion may altogether take the place of menstruation. Puech and Courty[9] have collected twenty-six cases of such vicarious menstruation, to which the cases of Landau[10] and Gautier[11] may be added. In the observation made by Jones[12] this vicarious menstruation manifested itself, during five years, by an abundant flow of milk lasting thirty-six hours every month.

It seems plausible that an appropriate stimulus can intensify this virginal secretion sufficiently so that it can nourish an infant. It is true that the older literature which abounds in instances of this kind can not withstand the test of scientific criticism. Yet there are cases reported by trustworthy observers which must convince us of the possibility of such an occurrence. The most widely cited instance, that of a girl of 8 years, who had suckled her infant brother for a month, was recorded by Baudelocque, and the young wet-nurse demonstrated before the Surgical Society of Paris in 1783.

Knott[13] vouches for three cases of abnormal lactation in nurse-girls who had charge of babies whose mothers were unable to carry out the function of maternity. "In each case the girl allowed the very uneasy bedfellow with whom she was thus supplied to play with her breasts and suck the nipples as the only possible way of procuring even a fragmentary night's sleep." In each, an increased sense of fulness and warmth in the mammary glands occurred and was followed in a couple of days by the appearance of a copious formation of milk. This, however, yielded very easily to simple treatment. Noël,[14] who has collected a large number of instances of abnormal secretion, mentions the case of a young married woman who had never had sexual intercourse. This woman took care during the day of an infant of six months, who, until then, had been nursed by his mother. As the child refused the bottle, she offered him her breast with the surprising result that the mammæ, heretofore rather small, increased in size and secreted a large quantity of milk, so that the child grew visibly and refused the mother's breasts after the latter's return from her trip. The nursing, at first quite painful, soon created an agreeable sensation. During the night, the engorgement of the breasts became very uncomfortable, so that the next morning was always expected with impatience.

These few references may suffice, particularly as they are corroborated by the observations of animal breeders. Thus virginal sheep, bitches and rabbits have occasionally been found to secrete milk. The stimulating cause in animals must be sought in rut and sexual intercourse. To select only one of the many writers on this subject, Harvey[15] stated that overfed bitches, which admit the dog without fecundation following, are nevertheless sluggish about the time they should have whelped, and bark as they do when their time is at hand, and also steal away the whelps of another bitch, tend and lick them, and fight fiercely for them. Others have milk or colostrum in their teats and are, moreover, subject to the diseases of those which have actually whelped.

An interesting observation on the relationship of mammary secretion and menstruation is recorded by Noël,[14] who had in his possession for a dozen years or more a female ape belonging to the family of Cercopithecus, a genuine *virgo intacta*, which spent its days in a cage. The menstrual flow appeared regularly every month, lasted three to four days and was preceded and followed by a copious, colorless vaginal discharge. After the menstruation in February, 1899, the animal, for some unknown reason, played with its breast, which, after a few days, produced a few drops of colostrum. These, under the combined effect of incessant massage and prolonged suctions, changed into an abundant supply of milk. The same procedure caused an identical result of the left mamma. This paradoxical lactation lasted for nine months, and, as the result of persistent manipulation on the part of the animal, reappeared after two months, and was still extant when Noël's report went to press fourteen months later. In summer the secretion was less than in cold weather. As long as the lactation was profuse the menstruation disappeared, only to occur regularly whenever the mammary secretion ceased or markedly decreased.

Instances of this curious secretion in the adult human male and in male animals have appeared sporadically in literature, but are not within the scope of this paper. It is possible that such cases belong to the class of pseudohermaphrodites. The reports are altogether too vague to permit of critical analysis.

The physiologic, that is, the most common, and at the same time the strongest, stimulus for the function of the mammary gland is pregnancy. As a rule, the formation of colostrum begins in the second month of gestation, the transformation into milk on the second or third day of the puerperium. The period of lactation lasts, on an average, one year, but ranges, in individual cases, within wide limits. It is, however, permissible to speak again of "abnormal mammary secretion in non-pregnant women" if the duration of lactation exceeds two years, when the organism of the child obviously has become independent of the milk supply from the mother.

Yet it is an altogether common occurrence to see lactation intentionally prolonged for an indefinite period of time. In the ethnographic work by Ploss[16] we find that this unnatural custom is distributed among all races and nations, all over the globe. I myself,[17] in my travels in Japan and Siam, have repeatedly seen a boy of 6 or 7 years interrupt his play or put the palm-leaf cigarette behind the ear in order to return to his mother's breast and take a sip of milk. In the poor and ignorant peasantry of middle Europe this custom is due partly to economical reasons, partly to the question of personal convenience. The most potent factor, however, very likely lies in the common popular error that lactation, and through it, amenorrhea prevents further conception.

There are several cases on record of extraordinary prolongation of lactation. Kamneff[18] reports a case of thirty-two years' duration, and Cazeau[19] describes another case in which an abundance of milk was secreted for forty-seven years. Even in the absence of an artificial stimulation by persistent suckling lactation may be abnormally prolonged. In the instance published by Arnheim[20] the patient, a woman of 26 years, was confined four years ago. Since then there has been a profuse mammary secretion which has resisted all known methods of treatment.

While, in the categories thus far discussed, we have encountered some sort of stimulus which could be held responsible for the abnormal mammary secretion, there is no such causation apparent in that strange complex of symptoms which make up the clinical picture of false pregnancy. Leaving aside the cases of purposely feigned pregnancy and postponing, for the moment, the discussion of pseudocyesis near the menopause, we know of this false or nervous pregnancy practically nothing but that either the wish or the fear is father to the thought. Yet such instances of secretion of colostrum, or even milk, from the breasts in false pregnancy are familiar to most obstetricans. A good illustration is the following case:

CASE 1.—*Patient.*—Mrs. T. A., 27 years old, married three years, had five miscarriages, the last of which occurred about the middle of February, 1904. (Syphilis?) She was extremely anxious to have children.

June 1, 1904: The patient noticed that her abdomen was growing larger. There was engorgement of the breasts containing milky fluid; regular morning sickness, at times vomiting; "fetal movements" for last six months. The patient believed herself pregnant. On examination a slight amount of colostrum was expressed from each mamma. The enlargement of the abdomen was found to be due to fat. The uterus was of normal size and consistency, in movable retroversion. There were positively no signs of pregnancy.

July 30, 1904: The patient had normal menstruations in June and July. The breasts still contained colostrum.

Oct. 15, 1904: The patient became pregnant in September, but passed out of my hands. I ascertained later that she again miscarried, was curetted, and died from septic infection.

A class by itself is formed by women in, or near, the climacterium with abnormal secretion from the breast. Tilt[21] found mammary irritation and swelling with the secretion of milky or glutinous fluid in 14 out of 500 women at menopause.

Billroth,[22] who assumed a very critical attitude toward most of the reports in literature, cited the case of the 59-year-old wife of a working man, who nursed, without a coincident delivery, her 9-months-old grandchild. At the beginning the child was nursed by its mother, who was, however, compelled to wean it. The child became so restless that the old woman, who had not menstruated for ten years, placed it to her own breasts to quiet it. Suddenly she felt piercing pains in both breasts, and on examination she found some drops of a milk-like fluid. The child was then zealously put to the breasts with the result of producing such a free flow of milk that it was exclusively fed by the grandmother. Another case in question mentioned by Billroth is that of a woman of 82 years. Rashid-ud-Din[23] records an old woman of 60 acting as wet-nurse to her grandchild. Incredible as these cases, which can easily be multiplied, seem, they are undoubtedly true. I, too, have seen several such instances in Siam.[17]

[22] *Diseases of the Female Mammary Glands*, Cycl. Obstet. and Gynec., 1887, ix, 44.

It seems a bewildering task to search for the cause of this phenomenon. According to Bloodgood,[24] there should be in the senile breast an atrophy of both parenchyma and stroma. The atrophy of the parenchyma is usually more marked up to its almost complete disappearance. The stroma never completely disappears. As the breast tissue disappears it is replaced by fat. It is due to this fact that, notwithstanding advancing age, in some well-nourished women, the breasts do not perceptibly decrease in size. In approximately 25 per cent. of the cases, however, a parenchymatous hypertrophy takes place in the senile breast. This senile parenchymatous hypertrophy may be divided into three stages: the adenomatous, ectasia and the adenocystic. As a rule, all three are present in different degrees. In the adenomatous stage one finds in the affected area more ducts and acini than in normal breast tissue. The stage of ectasia, which interests us most for the subject in hand, shows little dilated cavities filled with fluid or semifluid contents composed of débris of degenerated cells.

The appearance of "milk" in the senile breast may be due, in some cases, to this parenchymatous hypertrophy of Bloodgood. In others, as will be seen in the following cases, such a causation is certainly lacking.

CASE 2.—*Patient.*—Mrs. I. C., aged 39, mother of two children of 19 and 17, respectively; had no conception since. Menstruation was always regular, but scant; the last was three weeks before examination. The patient believed that she was pregnant because she "felt life," although the menses had never ceased. Her abdomen was growing larger and her breasts contained "milk." She was nauseated at times.

Examination.—Jan. 10, 1908. The patient looked much older than her actual age. There was a copious amount of colostrum in both mammæ, which were very flaccid. The vulva was senile; the uterus large and hard, in normal position; the adnexa normal. The patient was not pregnant.

CASE 3.—*Patient.*—Mrs. M. S., aged 42, had one confinement twelve years previous to examination; was in menopause for six months. She wanted to know whether she was pregnant.

Examination.—June 12, 1907. Mammæ were very flaccid; contained colostrum. The uterus was of hard consistency, in movable retroversion; the adnexa normal. The patient was not pregnant.

CASE 4.—*Patient.*—Mrs. C. P., aged 50, had a number of early miscarriages between the ages of 20 and 30 years. She married the second time eight and one-half months previous to time of examination. Menstruations were more infrequent of late, the last one six weeks previously. She stated that, since her second miscarriage, her abdomen was constantly growing larger, and that the configuration corresponded to "that of the last month of pregnancy." She felt persistent "fetal movements."

Examination.—Dec. 31, 1907. The patient was of medium size, rather stout, with an enormous deposit of fat in the abdominal walls. There were no signs of pregnancy or tumefaction of genital organs. Both breasts were large. The left mamma contained some fluid. The patient was informed of my diagnosis of obesity and climacterium.

Feb. 7, 1908: The patient had a slight menstruation at the end of January. She was still convinced that her confinement would take place within a few weeks. She asserted that the nipples of both breasts were more pigmented than before. "Fetal movements" were still pronounced. Examination was again negative as to the question of pregnancy. A gold-brown clear fluid was easily squeezed out of the left breast and presented, microscopically, the typical appearance of colostrum.

April 10, 1908: The patient informed me that she had taken up Christian Science and that the abdomen had considerably decreased in size; the fetal motions had ceased, and the milk had disappeared.

It is interesting to notice that the inevitable outcome in this case is erroneously attributed to the false doctrine of Eddyism. The patient completely overlooked the fact that I predicted the cessation of her symptoms three months previously and for this purpose recommended a change of her sedentary habits.

The foregoing are cases in which neither the desire for nor the fear of offspring, but merely the appearance of lacteal fluid gave rise to the thought of a belated pregnancy. The causal stimulus of this abnormal secretion, however, is entirely unknown. Yet there can be no doubt that only an appropriate stimulus is needed to bring about mammary activity in any case. This is conclusively shown in the cases in which, after normal delivery, lactation ceased, but was revived by persistent and energetic suctions. The interval of mammary inactivity is sometimes surprisingly long. Noël[14] cites several instances in which, even after a total absence of mammary secretion for four months, the child could be fully nourished by the breast.

An "appropriate" stimulus is not necessarily a mechanical one, that is, suction or traction.

The following case seems to indicate the possibility of a psychic influence:

CASE 5.—*Patient.*—Mrs. A. N., aged 40, was under my observation for eight years. She has a decidedly emotional temperament. During the last year she had frequent metrorrhagias for which she was curetted (in my absence) and took styptic medicines internally without lasting benefit. I saw her May 26, 1908, when she had been bleeding copiously for the last fifty-one days. The absence of any tangible cause, on repeated examinations and the excessive nervousness of the patient, called my attention to domestic difficulties of a serious nature under which she had labored for many months past. Three hypodermic injections of styptics, with administration of bromids, gave complete relief in twenty-four hours.

Since then these hemorrhages have returned once or twice immediately following a psychic disturbance, but were speedily checked on the patient's taking bromids. During these periods of excitement I also found that the breasts, which were not enlarged, contained a small amount of grayish fluid. On one of these occasions the patient exclaimed: "Whenever I hear a baby crying, I feel as though I could nurse it!"

Levene and Paderi[25] have observed that the subcutaneous injection of phloridzin, in some cases, is followed by an increased activity of the mammary glands. Misrachi[26] succeeded, three weeks after cessation of secretion, in producing a continuous production of milk by faradization of the mammæ. Dassier[27] and Biedert[28] noticed in climacteric women secretion of milk following a mastitis. These cases lead to the very interesting question of activity of the breast due to pathologic conditions. Tumors of the breast itself may be left entirely out of consideration. We are here mainly concerned with affections within the genital sphere.

[28] Quoted from Knapp: von Winckel's Handbuch, für Geburtshilfe, 1904, ii, part 1.

P. Mueller[29] has observed, in the University Clinic at Berne, fourteen cases of mammary secretion in sterile women, "in most of whom there coexisted some sort of a gynecologic disease." Of these, fibroids of the uterus are usually mentioned in connection with the reflex phenomenon in the breast. Thus, Säxinger[30] is given credit for observations of this kind. H. W. Freund[31] found in 25 out of 44 cases of fibroids colostrum in the mammæ. He believes that the alteration of the blood by the uterine tumor causes the mammary symptom. Because he never succeeded in producing secretion from the breasts by irritating, for weeks, the uterine cavity with strong galvanic currents, he excludes reflex through the nervous system.

Reports on this particular subject are exceedingly meager. It seems to me that the same cases are cited over and over again. Considering the enormous frequency of uterine fibroids, one would naturally expect the reflex symptom more often. I have in vain paid attention to it for a number of years, and so acute an observer as Billroth[22] states plainly that "in a tolerably large number of such tumors . . . ," he has "never witnessed such coincidence with abnormal milk-secretion."

Johnston,[32] reporting two cases of mammary secretion in false pregnancy, asserts that the occurrence of this abnormal activity with other disturbances usually associated with pregnancy began in one case at the same time that a hitherto normally situated uterus became retroflexed and was dependent thereon, for with the restoration of the uterus to its normal position, this condition became less marked and finally disappeared. In the case of Cramer[33] a woman of 33 had had a miscarriage nine years previously. Following this she suffered from an ascending gonorrhea, which resulted in fixed retroversion and sterility. At every menstruation thereafter there was an abundant lacteal secretion from the breast, for which, according to Cramer, the chronic inflammatory irritation of the uterus was perhaps responsible. Cramer operated on a woman of 40, eight years after her last confinement, for prolapse of the uterus with primary healing. The operation was followed by enlargement and copious secretion of the breasts.

Similar observations have been made in cases of obesity and in inflammatory diseases of the tubes and ovaries (Foges[34]).

Case 6.—*Patient.*—Mrs. E. S., aged 28, has a child a year old which she did not nurse. She had always been fleshy, but had grown very stout since the confinement. Her menses were regular, lasting from one-half to one and a half days, very scant. The last menstruation was two weeks before the examination. She had been nauseated since March. Her breasts were swollen, and for this reason she believed herself pregnant.

Examination.—June 19, 1908: The patient was an enormously fat woman with a gigantic abdomen. There was colostrum in both mammæ, but there were positively no signs of pregnancy. The diagnosis was obesity.

It would be desirable to publish, in future, every case of this kind and to subject it to scrutinizing analysis in order either to establish a mere coincidence or to throw light on a hitherto obscure chapter of the physiology of the genital organs.

The perplexity of our problem becomes even more apparent if we consider the influence of castration on the mammary glands. That the removal of both ovaries does not interfere with the secretion of milk in pregnant or puerperal women is conclusively shown by the numerous cases in which double ovariotomy was done before or after labor without impairment of lactation. One illustration may suffice.

Cramer[33] performed Cesarean section and Porro's operation on a woman of 36 for osteomalacia. This patient nursed her baby for eleven months. These facts are well known to animal breeders and, indeed, have been of practical importance to them. Lejoux, Venuta[35] and others find that castrated cows produce more milk than non-castrated ones. Oceanu and Babes[36] concluded from their experiments that double ovariotomy in goats not only prolongs, but also improves the secretion of milk; eliminating, for instance, the characteristic taste of the goat's milk at once. While in these cases, castration did not impair an already established secretion, there are, moreover, unimpeachable instances in which this operation actually produced lactation. Alterthum[37] found colostrum in the mammæ in 5 out of 18 cases after castration. Landau[10] has published a striking case. One and a half years after a double ovariotomy he found a free secretion of white milk for several months in a young woman of 26 who had never conceived. Gruenbaum[38] and Alsberg,[39] both from Landau's clinic, have added fifteen cases in which the removal of both ovaries was followed by mammary secretion which was either colostrum or milk. The secretion occurred both in multiparous and nulliparous women, independently of the age of the patients, provided they were still within the age of sexual activity. In some of these cases the ovaries were quite normal, in others totally diseased. This mammary secretion, then, was caused by the complete ablation of both ovaries. On the other hand, in those cases in which only the uterus or only one ovary was removed, or in which a remnant only of one ovary had been left behind, no secretion occurred. In Case 20 of Gruenbaum's statistics, the ovaries, save a small remnant on one side, had been removed in 1904. The patient had regular menstruations for three years. She was readmitted to the hospital because the ovarian remnant had degenerated into a cystic tumor. She was operated on for the second time in 1907, and the tumor radically removed. Eighteen days later a profuse secretion of colostrum occurred. The beginnning of the secretion, as a rule, was observed in the third week after operation, or later. It ceased, in some cases, after a few days or weeks; in others, it lasted as late as four months. An observation of my own may here be added:

Case 7.—*Patient.*—Mrs. A. H., aged 19, had had one confinement two years previous to operation mentioned below. She nursed her baby for four months. She suffered for eight months before the operation with intense pain in lower abdomen.

Operation.—Jan. 13, 1908: Abdominal panhysterectomy was performed for double pyosalpinx, abscess of left ovary, cyst of left parovarium, and an extensive pelveoperitonitis adhæsiva.

Postoperative History.—Convalescence was satisfactory, save a superficial suppuration of the incision.

Feb. 2, 1908: As the symptoms of artificial menopause (hot flashes, etc.) were pronounced, ovarian extract, 5 grains, t. i. d., was ordered.

Feb. 7, 1908: There was copious secretion of a grayish fluid from both breasts which heretofore had been absolutely dry. Microscopic examination revealed typical colostrum.

Feb. 25, 1908: The patient was discharged in good health. Mammary secretion was still present.

Epicrisis.—The interval of five days between the first administration of ovarian extract and the appearance of colostrum in the breasts was too short to suggest any influence from the organotherapy. For this reason, the case must be classed with those of abnormal mammary secretion following castration.

Atrophy of the ovaries may produce the same phenomenon. Foges[34] observed several patients who, after parturition, had amenorrhea for a number of years, yet exhibited an abundant secretion of milk in spite of the fact that they had never nursed their children. The following observation of my own belongs to this category:

Case 8.—*Patient.*—Mrs. H. L., 25 years old, had been married for three years without conceiving. Her menses were very irregular, about once in three months, and very scanty.

Examination.—The patient's breasts were small, more like those of a girl of 14. The vagina was very short, and the vaginal vaults were unusually shallow. The uterus measured only 6 cm. Both ovaries were apparently normal to the touch. In every other respect the patient seemed to be normally developed.

June 15, 1908: The patient asserted that whenever menstruation would be due without actually occurring, the breasts would feel sore and contain fluid. This being a menstrual date, I found a large quantity of colostrum in both mammæ.

September 3: The patient had, after an amenorrhea of two months, just one drop of bloody discharge on each day for four consecutive days, about a week ago. On slight pressure a thin fluid squirted out of both breasts.

Halban[7] explains all these cases by the theory that the ovary, by its internal secretion, brings about the development of the mamma into an organ capable of function. As long as the glandular substance of the mamma develops, secretion of milk does not occur. When the growth of the mammary gland ceases, retrogressive changes set in which manifest themselves by production of milk. The growth of the mamma is controlled by the ovary. Without the ovary there is no further growth, and the mamma undergoes involution. Thus, if the ovaries are removed or become atrophic, involution of the mamma is no longer held in check, and lactation may ensue. In pregnancy, when the ovary is supposed to remain inactive, the function of the ovary is taken up by the placenta. The latter, too, has an internal secretion. The substances originating in the placenta have the same effect on the mamma, namely, that of preventing retrogressive changes. After birth, the placenta no longer exercises its inhibitory influence, and milk appears. In this manner the occurrence of lacteal secretion in the puerperium is explained as well as that after castration and in the climacterium.

This explanation would be plausible enough were it not for the following observation of Cramer.[40] In a woman of 21, atrophy of both ovaries was supposed to exist because of amenorrhea since her only confinement two years previously. Transplantation of two healthy ovaries from another woman was performed. A few weeks after the operation there was a secretion from both mammæ, which hitherto had been absolutely dry.

Abnormal outward appearance of milk may be mentioned, though it is in but loose connection with our subject. Blue milk owes its color to the development of the *Bacillus pyocyaneus.* Red milk is due to the presence of the *Micrococcus prodigiosus.* Yellow milk is also produced by the growth of a bacillus. Sheild,[41] from whom these notes are taken, also speaks of a case of green milk, the color of which was not due to bile pigment, but very likely to an aromatic body produced by bacteria.

From these cases those instances must be distinguished in which blood was secreted by the mamma. The presence of malignant tumors of the breast should first be excluded. In a few, though not well authenticated cases, vicarious menstruation occurred from the mamma. Rarely hysteria produces this remarkable phenomenon.

Skutsch[42] recently demonstrated a case of this sort. Another case with all symptoms of pronounced hysteria was published by Chipault,[43] who also gives the scanty literature on the subject. The true hysteria breast is characterized mainly by a vasomotor edema which causes ecchymoses and hemorrhage. It is quite important to recognize the real hysteric nature of these hemorrhages in order to avoid operations.

The question of the primary cause of mammary activity has been repeatedly touched on in the foregoing. The clinicians have been always inclined to assume an influence of the nervous system on lacteal secretion, and they have based their views mainly on the observation that the secretion of milk is sometimes greatly altered by such emotions as passion, grief, or mental depressions. The text-books on physiology arrive at similar conclusions, principally from analogy between the mammæ and other glands, the secretion of which is subject to nerve stimuli.

Kurdinowski[44] assumes that the pregnant uterus presses on neighboring organs and nerves, producing a constant mechanical irritation which is transmitted to the mamma. The same effect may occur if the uterus is enlarged by fibroids or by a combination of metritis and retroflexion.

The exact experimental proof, however, is still lacking. It is true that Roehrig,[45] Laffont and others, from their researches, have asserted that irritation of the peripheral nerves of the mammæ actually increases the activity of these glands, but their results have been challenged and disproved by the majority of observers. Ribbert's[46] experiment is particularly noteworthy. Ribbert extirpated the mamma in a young guinea-pig and transplanted it beneath the skin of the ear. When the animal became pregnant the transplanted gland developed normally and afterward produced milk. A similar result was obtained by Basch.[47] In a bitch in which the left spermatic nerve and the celiac plexus had been resected previously, thus depriving the lowermost mammary gland of both the peripheral and sympathetic nervous impulses, the gland was transplanted on the back. After some time pregnancy occurred. The gland became hypermic and well-developed. After delivery there was absolutely no difference in the milk secretion of the transplanted gland and that of the other mammæ of the animal.

[46] Ribbert: Ueber Transplantationen von Ovarium, Hoden und Mamma, Arch. f. Entwickingsmech. d. Organ., 1898, xii, 688.

It must, then, be accepted as an established fact that the specific function of the mammary gland is independent of the nervous system.

Starling[5] injected extracts made from different parts of the immature rabbit fetuses into virgin rabbits and thereby produced well-marked hypertrophy of the mammary glands similar to that observed during the earlier stages of pregnancy. He, therefore, concludes that "the growth of the mammary glands during pregnancy is due to the assimilatory or inhibitory effects of a specific chemical substance produced in the body of the fetus and carried thence through the placenta by the fetal and maternal circulations. The removal of the inhibitory stimulus at the end of pregnancy determines the spontaneous break-down of the built-up tissues, i. e., activity which in these cells is expressed by the formation of milk."

The ingenious and painstaking researches of Halban[5, 6] have already been referred to. According to Halban, the etiology of mammary function has nothing to do with the fetus, but this function is due to the internal secretion of the ovary; in pregnancy, the function of the ovary is temporarily assumed by internal secretion of the placenta. This theory of Halban's throws much light on a problem of science which hitherto has been very obscure, despite the enormous number of investigations which have preceded his. H. de Rothschild[18] has collected up to 1899 not less than 8,375 publications on the subject.

It is the object of this paper to call attention to the fact that further accurate observations are needed to settle certain mooted questions. We have seen, in the foregoing, that lacteal secretion does not only occur in pregnancy and puerperium but that it also may appear in the newborn, in the growing child, in the adult virgin and in the old woman. It may be prolonged indefinitely after childbirth, and may be associated with certain pathologic conditions within the genital sphere. The last named phenomenon, in particular, demands earnest consideration, and the hope is expressed that a discussion on this subject will bring forth experience gained in this country. Aside from the intense scientific interest in the etiology of lacteal secretion, there is also considerable practical importance attached to abnormal activity of the mammary glands, and a thorough knowledge of atypical function of these organs is indispensable to the expert in medicolegal practice.

Linmar Building.

DISCUSSION.

Dr. W. O. Henry, Omaha: *I saw a case the features of which emphasize what Dr. Gellhorn has said. The case was that of a woman 36 years old, the mother of one child 12 years old. She had some inflammatory trouble and both her ovaries and tubes were removed. Shortly thereafter she had a regular monthly formation of milk in the breasts lasting for from four to five days. This continued for over a year and then ceased.*

Dr. Bernard Cohen, Buffalo: *A few years ago I saw another case similar to the one reported. The case was that of a girl of 17 who had two supernumerary breasts, one over the right iliac region and the other at the lowest right rib. At each menstrual period there would be secreted a fluid resembling cholesterin which would last four or five days and then disappear. I observed this case for about two years and then lost sight of the patient.*

Dr. Joseph B. De Lee, Chicago: *There is no doubt of the diagnostic value of the presence of milk in the breasts in pregnancy. All the text-books note that as one of the diagnostic signs as well as the associated mammary changes, particularly the expression of colostrum from the nipple. Very early in my own experience I found that sign so fallacious that I began to surround it with a great many qualifications. Surrounded by these restricting qualifications the sign still has a certain value in the differential diagnosis between pregnancy and other abdominal conditions. Absence of the mammary changes, however, is of more diagnostic value than the presence of the sign. It is reasonable to suppose, in a contested case, if the breasts show no changes after four or five months' observation that pregnancy does not exist. The presence of a small amount of colostrum can be demonstrated in a breast that shows no other changes and these other changes are more diagnostic than the colostrum. These changes are enlargement of the breast, increase of glandular tissue, puffiness of the areola, and the enlargement of the so-called tubercles of Montgomery.*

Dr. Frank Hinchey, St. Louis: *The subject is of great interest from the medicolegal standpoint, but it has impressed me particularly from the point of the etiology of the milk secretion and the theory of Halban. His theory is interesting but it does not cover all the points in abnormal secretion. The abnormal secretion found in the male and female shortly after birth might, as he said, be due to some remains in the blood of the fetus of a placental or ovarian secretion circulating in the mother's blood, but it does not explain the presence of milk in the mature male breast. It is known that good biologists have reported cases in unimpregnated females and in male animals in which there could have been no placental stimulation on the one hand and no ovarian secretion on the other. In the male it might be supposed that the condition was due to hermaphrodism, or partial hermaphrodism, but investigators have eliminated that factor. Neither does Halban's theory explain the condition in animals that have no placenta, the mammals which lay eggs having a large yolk. These eggs are laid as the eggs of birds are laid and there is no placenta, therefore no placental stimulation, yet in them we have a milk secreted from the walls of the pouch, so that the theory fails to explain these interesting cases. I do not know that we can eliminate the question of stimulation from the nervous system, because in the case of transplanted breasts we no doubt soon have a connection with the nervous system, just as we have when skin is grafted. The nervous attachment becomes apparent in the grafted skin after a short time, by the production of sweating under the influence of nervous impulses, just as in normal skin elsewhere.*

Dr. George Gellhorn, St. Louis: *I was so anxious to keep within the time allotted that I omitted to mention the curious phenomenon of the secretion of blood from the mammæ. Such instances have been observed by German and French investigators. The hysterical nature of these hemorrhages from the breast is of great practical importance because we must in these cases avoid operation.*

Tuberculosis of the Testicle.—Delaup, in the *New Orleans Medical and Surgical Journal*, states that tuberculosis, whether apparently localized in the testicle or elsewhere in the body, is always a disseminated affection which can not be amputated. His choice of operation, therefore, is epididymectomy, unless the disease has progressed too far and the testicles can not be saved.

ABLATIO PLACENTÆ.

PREMATURE DETACHMENT OF THE NORMALLY SITUATED PLACENTA.*

RUDOLPH WIESER HOLMES.
Associate Professor of Obstetrics and Gynecology, Rush Medical College.
CHICAGO.

SYNONYMS.

Accidental Hemorrhage (Rigby, 1776), *Premature Detachment of the Normally Situated Placenta*, Ablatio Placentæ—Placenta Ablata (Holmes, 1901).

DEFINITION.

Ablatio placentæ is the separation, partial or complete, of the placenta from the upper uterine segment during pregnancy, or during labor before the completion of the second stage, due to some pathologic state of the uteroplacental union or violence done the organism.

FREQUENCY.

In spite of the close statistical study of obstetric complications in general, the subject of ablatio placentæ has been greatly neglected or ignored by obstetricians. In some clinics the condition has not been recognized; in others it is held to be of such rare occurrence that an example has not been observed in an enormous clinical experience; while in others it is not of very unusual occurrence. The wide disparity found in studying different hospital reports suggests that the discrepancies are due to faulty interpretation of symptoms or incorrect observation. In investigating this subject one can but be impressed with the enormous mass of literature on placenta prævia, and the relative paucity of material on ablatio placentæ. A considerable experience with antepartum hemorrhages has clearly convinced me of the fact that the latter is almost always mistaken for the former, especially if the placenta dips only slightly below the retraction ring.

Spiegelberg, one of the most diligent observers of obstetric anomalies, in his text-book describes placentæ which demonstrate clearly the presence of old blood clots on the maternal surface: sometimes these clots are firm dark particles of blood, varying in size from that of a small coin up to that of a hen's egg or even larger; again, the coagula may have been so old that the hemoglobin has been entirely absorbed, leaving a putty-like substance to denote the site of a former hemorrhage. Oftentimes, these clots are buried in a depression on the maternal surface of the placenta. In this connection, Brodhead was able to find 7 instances of such pathologic hemorrhage in 1,000 histories. These cases are merely of interest to the pathologist. On the other hand, the bleeding may be of such import that the woman and her child are placed in the sorest jeopardy. It is to such cases that I shall devote my description.

The Rotunda Hospital of Dublin in seven years had 74 cases of accidental hemorrhage (ablatio), with a ratio of frequency of 1 in 121.58. During the same period the staff observed 55 cases of placenta prævia—a ratio of 1 to 163.58. The Rotunda is the only clinic which meets ablatio more frequently than placenta prævia.

Hofmeier, of Würzburg, in Winckel's "*Handbuch der Geburtshülfe*," maintains that ablatio is incomparably less frequent than prævia, and quotes Goodell to the effect that he could find only 106 examples in the literature, and that Brauns in 1893 could only get 51 additional cases. As Hofmeier, so nearly all writers, misled by the title of Goodell's paper, have blindly accepted the statement of Goodell of the excessive rarity, he being led astray by the nomenclature of Baudelocque, who introduced the name of "concealed accidental hemorrhage." Yet, of Goodell's 106 cases 27, or approximately 27 per cent. had external bleeding in the course of the disease. In my previous contribution on this subject I was able to collect 73 examples of concealed hemorrhage, which, added to the 78 of Goodell, makes a total of 151 of the absolutely concealed type. As I see it, absolutely concealed hemorrhage is exceedingly rare, but the patent examples are not so infrequent. The combination of the two types, absolutely and relatively concealed hemorrhages, probably occurs at least half as frequently as placenta prævia.

ETIOLOGY.

The causes of ablatio naturally fall into two general classes—the predisposing and the direct: The chief predisposing factors are age, multiparity, advance of pregnancy, and the physiologic structure of the serotinal portion of the placenta, and its site.

In my previous paper[1] I showed that in the three decades of the child-bearing period—that is, in the ages, 16 to 25, 26 to 35, 36 to 45—ablatio occurred 17, 53.7 and 29.8 per cent., respectively; the fact that only 10 per cent. of labors occur in the last decade is strongly suggestive. It was found that of the 156 women whose data were given that only 30 were primiparous, or 19.2 per cent.; as primiparous labors comprise 25 to 33 per cent. of all deliveries the relative immunity is evident. In 157 patients the length of gestation was as follows: 6 in the fifth month, 4 in the sixth, 29 in the seventh, 62 in the eighth, 52 in the ninth or at term. Read has shown that labor comes on at term in placenta prævia in only 19 per cent., while in ablatio, according to my figures, labor occurs at term in 33.1 per cent., or according to Goodell in 50.5 per cent. A great part of this may be dependent on the fact that with the advance of pregnancy, *pari passu*, the conditions increase which make the complication more severe, therefore, more easily diagnosticable. Jacquemier contended that the immense ramification of the uterine sinuses, and the relation to them of the small caliber of the ovarian and uterine veins predisposed to blood stasis: conditions which produced engorgements or congestions would tend to disrupt the delicate uteroplacental union. Cazeaux believed that the double placental circulation was operative: Gendrin thought that uterine contractions could cause the separation with the resultant hemorrhage. It is of interest that Hofmeier lends credence to this obsolete idea. Saenger very properly has disputed the contention of Gendrin.

The direct causes are of greater import and of more scientific worth. There may be no question but that ablatio may be directly due to violence applied to the abdomen, or to other parts of the body. No arbitrary rule may be laid down as to the severity of the trauma necessary to disrupt the uteroplacental union. We all know of women who have fallen down stairs, have been violently kicked or hit in the abdomen without any uterine reaction whatsoever: per contra, women have had very trivial injuries which have determined premature labor or resulted in ablatio. I am firmly convinced that, barring certain severe contusions, especially of the abdomen, the usual accident attributed as the cause is merely contributory and subordinate to the pathologic uterine disease. J. Ramsbotham, long ago, put this clearly, and showed his prophetic mind by enunciating this: "The attack rarely follows the immediate application of a supposed injury; a lapse of some time usually intervenes."

PATHOLOGIC CAUSES.

It has been already shown that ablatio is peculiarly a complication of multiparous women of the second and third decade of the child-bearing period, which undeniably is due to the wide prevalence of metritis and endometritis. Just as such inflammatory processes bear a causal relation to metrorrhagia and menorrhagia, so the decidual endometritis which is a direct sequence often *manifests itself in antepartum* hemorrhages of the decidua vera and serotina. An old specific endometritis may be the foundation of the apoplexy of the pregnant uterus; a puerperal endometritis of one lying-in period or of a criminal abortion may account for the ablatio in a subsequent pregnancy. So the gonococcus, streptococcus and staphylococcus will often be the direct causal factor. Reinicke and Pick have found, as have others, sclerosis of the uterine arteries in the non-pregnant; if pregnancy should supervene in such sclerotic subjects, it is logical to believe that the atheromatous vessels may be the determining cause of a retroplacental apoplexy. Winter added much to our knowledge of the etiology of ablatio when he depicted the intimate relation between decidual and placental inflammations concomitant to renal inflammations. Hennig and Weiss corroborated this. One of my cases had such a complexus of pathologic findings. Rousseau-Dumarcet in 14 cases of ablatio had 11 with renal changes; likewise, in the Clinique Baudelocque the same combination was found in 24 of 31 cases. Further in my statistical study 20 reports showed some form of nephritis.

When we directly consider the placenta we find that it also is subject to inflammations which have an important bearing on the subject. Since the day of Rokitansky the profession has known of placentitis: he found placentæ with inflammatory infarcts, both with and without placentary hemorrhages. We all know how common is the fibrosis, the calcareous degeneration, and the fatty degeneration of the placenta. Kaltenbach and Veit both declare that all placentæ must have a serotinal inflammation to permit of a premature separation: Fehling and Schroeder declare that we must go further before we may substantiate the assertion that there is a difference between infarcts or inflammations accompanying albuminuria, and those in which the latter does not exist.

PATHOLOGIC ANATOMY—DYNAMICS.

Goodell attributed the blood retention in cases of absolutely concealed cases of ablatio to four causes:

1. When the placenta is centrally detached and the blood is restrained by a firm adhesion of the placental border.
2. When the adhesion of the membranes is such that blood accumulates between the uterine wall and the chorion.
3. When the membranes rupture near the placenta, and the effused blood commingles with the liquor amnii (there is no record of such a form)
4. When the presenting part so plugs the lower segment that blood may not escape.

I have added to this list instances of conglutinatio *orificii externi*. When the blood has been dammed up under the placenta for some time a distinct depression will frequently be found on the maternal placental surface; this depression may occupy a very considerable area of such surface.

The condition of ablatio closely resembles the mechanics of the typical abortion; this phenomenon is so strongly suggestive that we might well say that ablatio is an abortion in the latter months of pregnancy. We appreciate the fact that the usual abortion is ushered in by hemorrhage within the decidua, or between it and the uterine wall; the clot acts as a foreign body, stimulates contractions, and eventually the expulsion of the ovular mass. The analogy is perfect! In ablatio the retroplacental hemorrhage of slight degree determines a commensurate separation of the placenta to permit the formation of the cavity to contain the blood. Let uterine contractions occur: at once this imprisoned blood is compressed; the compression determines additional placental separation; the cavity, increased by this act, is filled by additional blood during the interval of contraction; and thus a mechanism similar to Schultze's mechanism for the third stage is inaugurated. If these small, repeated effusions of blood occur near the placental periphery, soon the border is reached, and the free blood, or more probably the serum expressed from the clot, finds its way to the os outside of the membranes.

SYMPTOMATOLOGY.

The sole pathognomic sign of ablatio is the local and systemic evidence of hemorrhage. The systemic effects of blood loss in ablatio are identical with those of other conditions associated with internal hemorrhages. If there be no external manifestation of bleeding the diagnosis may be difficult—but the diagnostician should always bear in mind that a patent bleeding is merely a corroboratory symptom of the premature detachment of the placenta. The cases which present either occult or patent bleeding offer such clear clinic pictures that one may well divide all cases into two types. Some seven years ago I was so impressed with this fact from a study of over three hundred case histories that I divided the cases into two classes, characterized by absolutely concealed and relatively concealed bleeding, respectively. That such a classification is a valid one all will admit who have studied this question from clinic experience and reading descriptions of the complication. The amount of blood which passes from the vagina is never commensurate with the amount which has left the woman's vessels. So far as my knowledge goes—and this is based on a very extensive review of the literature as already stated, and an experience of 9 clear, typical examples—every case which is characterized by external bleeding has more or less blood retained in the uterus. Further, from the brief review of the dynamics, it is clear that all cases begin with absolute concealment of the hemorrhage, and later may develop a patent hemorrhage. A cardinal principle in ablatio is that one never should gauge the jeopardy to the mother or child by the amount of blood which appears at the vulva—systemic effects alone must be considered. It is not inapt to state that the relatively concealed type is a terminal stage of the absolutely concealed form.

As a corollary to the hemorrhage are two signs of great significance. One is the distention of the uterus which may be diffuse or local. If local there will be a bulging of the uterine wall over the placental site; this is the so-called accessory tumor. As over one-half of all placentæ are on the posterior wall of the uterus, this sign may be elicited in less than half of the cases in which it is typically developed. The accessory tumor is the result of the retention of a large retroplacental hemorrhage with adhesion of the periphery of that organ. The uterus, which is equally distended, may be tense, hard like a contracting uterus, or may be flaccidly filled with retained blood. The other characteristic finding is the escape of a thin fluid from the vagina; this is the blood serum which has been expressed from the clot. This serum must not be confused with the liquor amnii, which it oftentimes closely resembles. In sharp contrast to the painless appearance of hemorrhage in prævia is the frequent precursory pain in ablatio. As in ruptured extrauterine pregnancy, so in ablatio, the first premonition of impending trouble is pain, or, perhaps, a synchronous feeling of faintness, nausea, or even entire loss of consciousness. The pain may be slight, diffused, or localized, and typically it is localized over the accessory tumor, if it be present; the pain is not infrequently of excruciating severity, with exacerbations if contractions be present.

DIAGNOSIS.

I take the stand that the difference between instances of absolutely concealed and relatively concealed hemorrhages is one of degree only, and that this difference is largely the difficulty of diagnosis. The two conditions are allied in their complexus of symptoms; there is not a sign or symptom of one which is not equally characteristic of the other, except that in the latter the bleeding is evident to the eye. Yet, if active uterine contractions set in, the obstruction which retains the blood may be swept aside, and an occult bleeding becomes evident. The graphic picture is the rather sudden onset of pain, nausea to actual emesis, possible brief tumultuous fetal movements; gradually the pain may become intense, of a stretching, bursting nature; the woman feels that her abdomen is distending; with the aggravation of symptoms unconsciousness may supervene, signs of anemia, the development of the accessory tumor, the escape of serum or of blood; the palpation of the placenta is utterly impossible by local examination. Further, with the expulsion of the child, or at any rate with the delivery of the placenta, there will be considerable amounts of dark clotted or fluid blood. Perhaps a depression which contains coagula may be found on the placenta; if the depression is absent, then, at least a portion of the placenta giving unmistakable evidence of the premature separation should be found; if some period of time has elapsed between the separation and delivery of the afterbirth, this separated area will be found darkened, of a markedly different color from the contiguous portions. The opening in the bag of waters will be at least three inches from the placental border.

Placenta prævia is diagnosticated by the palpation of the placenta, the onset of hemorrhage without premonition and without any pathologic pain; the presenting part is frequently dislodged from the inlet; if the prævia be a high lateral one a differentiation only may be made by a careful macroscopic inspection of the secundines.

In rupture of the uterus the accident is unusual before advanced labor; almost invariably there is the history of strong contractions with the sudden cessation as the rupture occurs. The presenting part recedes from the inlet, and if the rupture be extensive enough the fetus escapes into the abdominal cavity, which permits the palpation of the fetus with remarkable readiness. This is in sharp contrast to ablatio, for almost always in the latter the fetal parts are palpated with great difficulty, or palpation will be found quite impossible.

A fibroid only would be brought into consideration if the import of the accessory tumor were not recognized.

In simple vertigo or loss of consciousness from various causes there is no anemia, there is no pain; the picture of faintness is quite different from the cerebral anemia incident to a severe hemorrhage. If in doubt the hemocytometer and the hemoglobinometer will clear up all doubt.

PROGNOSIS.

In placenta prævia, other things being equal, the jeopardy to the mother and child varies directly as the degree of placental presentation; and this danger generally may be clearly predetermined. In ablatio the amount of placental separation present can not be estimated; in fact, we have no means of fixing this amount, neither have we any criteria as to how much further the separation may extend in the course of the treatment. At best, this fact is of relatively slight importance—our principal concern is the amount of blood lost, and its effect on the woman's bodily functions. This by careful observation may be fairly accurately fixed. As we have a broad field, from the pathologic examples recognized only by postpartum inspection of the placenta up to the fulminating cases terminating before aid may be secured, which have the uterus enormously distended with blood, we can not give an average mortality. In one there is no direct danger; in the other there is a death rate which exceeds any obstetric complication. In determining, therefore, the prognosis we must necessarily base our estimate solely on those cases which are of real clinic significance. In this class of patients the prognosis is dependent on the celerity with which the diagnosis is made, and the rapidity and skill used in the delivery. Goodell, in 1871, gave the mortality as 50.9 per cent. and 94.4 per cent. for mother and child, respectively. I found that there was a mortality respectively of 32.2 and 85.8 per cent. Of 39 absolutely concealed cases I found a mortality of 23 per cent; the fatality for 150 patent hemorrhages was 34.6 per cent. Goodell gave figures which undoubtedly are relatively more correct—52 and 41.3 per cent., respectively. I have had 9 severe cases of ablatio. Two patients died; one died directly after delivery, from the excessive anemia; the other, directly after the onset of the trouble, which first manifested itself by a flow of serum, had an eclamptic seizure; she reacted well from the hemorrhage, but died nine hours after the first sign from eclampsia.

TREATMENT.

I have convinced myself that he who will be aggressive in action will save most lives. When certain of the diagnosis means should be taken to deliver at once. The methods of dilatation appropriate for ablatio are curtailed by the fact that not only is the field of operation obscured by hemorrhage from the cervix, but the dislodgment of the presenting part or the rupture of the membranes may bring forth the disconcerting and obscuring flow from the uterine cavity. Therefore, two methods are open to the obstetrician, manual and instrumental, the value of the latter being questionable. It is a fortunate circumstance that the cervix is usually peculiarly softened and the os dilatable in ablatio, due to the softening effects of labor, or the anemia, or both. As the eye is an unnecessary aid to manual dilatation, this method offers distinct advantages over the other procedures for dilatation. Vaginal Cesarean section would be an ideal method in those cases in which the cervix is still unprepared for delivery, *if it were not* for the blood escaping from the uterine cavity. Vaginal Cesarean section should not be performed when the operator can not see what he is doing. Again, the additional blood lost from the incisions might be just the amount which would determine the death of an already anemic woman.

When full dilatation is secured, version, forceps or craniotomy should be used, the choice being determined by the condition present. When version is elected, it should be borne in mind that extraction must be immediately performed; if delays occur in the course of the extraction, the partially emptied uterus may fail to contract, the actual cavity of the uterus may become filled with fresh blood, and this hemorrhage may be the direct cause of death. As when ablatio occurs nearly all the babies are dead from the asphyxia incident to the placental separation, the more general employment of the cranioclast is to be strongly recommended.

De Lee, in a recent communication, suggested the se of the Stowe bag, with the idea that the uterine ıvity could be filled with saline solution, thus rais- ıg intrauterine pressure, restraining the effused blood until full dilatation was secured by hydrostatic pressure, when extraction could be carried out. The principles of the use of the bag are in a measure those suggested by the advocates of the tampon. The tampon and bag will convert the patent into an occult hemorrhage. The bag, like the tampon, is too slow and uncertain in its action. Theoretically, the tampon and bag will raise intrauterine pressure until it is as high or higher than that of the blood pressure, when bleeding will cease. This would be true clinically if the uterus were an inelastic cavity; but, as the uterus is a contractile organ, its cavity must be larger in the interval of contraction than during the height of its activity, so, no matter how much saline solution could be placed in the uterus, or how effectually the blood has been restrained, intrauterine pressure never could be raised to the point at which the uterus was full.

Abdominal section has been suggested and employed as a means of delivering the woman. For hospital patients who have actually rigid cervices this method offers far greater advantages than vaginal Cesarean.

If the placenta is not delivered with the child, then immediate manual removal should be employed, with the removal of all clots from the uterus. As the uterus is so constantly atonic during and after delivery, no time should be wasted in questionable methods of securing retraction and arrest of a possible postpartum hemorrhage, but the uterus and vagina should be tightly packed with antiseptic gauze. This is so important that I hold that cases of ablatio not given the benefits of a uterovaginal tamponade have not been adequately or properly handled. The excuse of some physicians that the gauze is not at hand is as nonsensical as for a man to say that he did not provide himself with a scalpel for a laparotomy.

I can not emphasize too strongly the absolute necessity of having an assistant who will use firm fundal compression during the extraction of the fetus and after the tamponade until the uterus is firmly contracted.

A few words concerning the routine treatment of hemorrhage: Saline solution should be given early, before delivery, while the preparations are being made for delivery, and afterward if it is needed. The amount of saline solution should be about double the estimated blood loss. The saline solution may be increased in efficiency by adding to it adrenalin solution—ten drops to the one or two quarts. General stimulants, such as strychnin, digitalis, coffee, camphorated oil, ether and whiskey, serve their purpose.

Finally I approach the question of ergot with some diffidence, for my opinion on the use of ergot in this one complication is at variance with that of my usual teaching, as well as that of others. The hemorrhage of ablatio is the one condition permitting the use of ergot before the uterine contents have been delivered. The ergot never must be given in full doses. The fractional doses of ten to twenty minims may be repeated two or three times in the course of an hour if the uterus be atonic. *The atonic uterus is the sole indication;* after delivery all these patients should be given full doses to secure a permanent retraction of the uterus.

412 North State Street.

ABSTRACT OF DISCUSSION.

DR. JOSEPH B. DELEE, Chicago: Dr. Holmes has suggested the name of "ablatio placentæ" for the premature detachment of the normally implanted placenta to go alongside of the term of placenta prævia. Premature detachment of the normally implanted placenta is rather a long term. The term "ablatio," the English of which is ablation, did not appeal to me, however, because we use it to signify the carrying away of a part, whereas the intention in this connection is to give the idea of tearing loose. In the terms to cover the idea of premature detachment of the normally implanted placenta we wish to have, first, the idea of suddenness; second, the idea of prematurity; third, the idea of the normal position of the placenta; and fourth, the idea of violence. There is no Latin term that would go with placenta and cover all these points. I have made a diligent search and have spoken to several Latin scholars. The nearest approach to it is, *abruptio placentæ*, which means a tearing loose, a breaking away from. Dr. Holmes is right when he says that ablatio placentæ is more common than placenta prævia. In my experience it is a little over twice as common, there being fifty-nine cases of placenta prævia to twenty-six of ablatio placentæ. Not infrequently the placenta is located low in the uterus and a portion of the placenta is over the internal os, but beyond the reach of the finger. This becomes detached, so that we might perhaps speak of a mixed form; without doubt some cases of placenta prævia and ablatio placentæ are confused. When the discussion arises in regard to the interruption of pregnancy in the latter months of gestation in cases of chronic nephritis, the detachment of the placenta should be borne in mind and the danger of death of the child from this cause should be taken into consideration. I do not think that Dr. Holmes emphasized the question of shock sufficiently. Without doubt the shock is caused by the sudden loss of blood, but the rapid and painful distention of the uterus produces a condition of shock which is not commensurate with the amount of blood lost. The frequency of the accessory tumor I believe is exaggerated. I believe that treatment consists in the most rapid emptying of the uterus consistent with safety. If the patient is in a hospital and if the conditions for rapid delivery from below are not ideal, the abdominal Cesarean section offers the quickest and safest method of emptying the uterus. If, however, a rapid dilatation of the cervix can be made, that is the ideal treatment. If the patient continues to bleed a firm tampon should be placed in the uterus. I have performed vaginal Cesarean section three times with success in cases of abruptio placentæ.

Dr. S. Straus, New York: I think that vaginal Cesarean section is the method *par excellence* for emptying the uterus in almost every case of this kind. By this method the operator has the field of operation directly under his eye. In one case of hemorrhage in a pregnant woman following accident in which separation of the placenta was caused there was immediate shock. The condition was recognized from the symptoms of anemia, and investigation showed that the uterus was closed with no evidence of external hemorrhage. The woman was a multipara. I saw her about two hours after the accident and delivered her easily by vaginal Cesarean section.

Dr. O. S. McCown, Memphis, Tenn.: In November, 1907, I had two cases of ablatio placentæ in private practice. The first case was that of a woman, aged 28, in a third pregnancy. The two previous pregnancies had been normal and had terminated normally. I had examined the urine of this patient two weeks previous to the time I was asked to see her and had found it normal. I was sent for at midnight and found the woman in labor, but with an elevated temperature and a fast pulse of low tension. The physical examination revealed nothing except the absence of the fetal heart sounds. The cervix was dilated nicely. The pains were as they should be, and labor apparently was progressing in a normal manner. In the course of an hour the nurse called my attention to the fact that there was some bleeding. Investigation showed that it was not a case of placenta prævia, and I diagnosed it as premature separation. Delivery was done as quickly as possible without help and the child was found to be dead. This was at the seventh month, and the skin slipped off. The woman was evidently septic at the time. The patient died on the fifth day without ever having an ounce of urine in the bladder. There was never enough urine in the bladder to make an examination of. The second case, which occurred almost in the same week, was that of a woman, aged 33, in her third pregnancy. The two previous pregnancies had been marked by pain in the arms and shoulders and were terminated in a normal manner with living children. I had seen her in these pregnancies and had made the diagnosis of a mild grade of toxic neuritis. I found nothing abnormal in the urinary examinations. At the eighth month I was sent for and found the woman in labor. The abdomen was greatly distended, and the distention was uniform. The general condition was good, as was the pulse. It was said that two weeks before she had felt acute lancinating pain. I made the diagnosis of internal hemorrhage with probably premature separation. Delivery was accomplished, but the baby was dead, evidently dead before I saw the patient. The whole mass of the placenta and the body of the child came at once with an enormous quantity of clots and liquid blood. After forty-eight hours the urine began to come, and, while it was highly albuminous, it gradually increased in quantity, and the patient went on to a good recovery. I must admit that according to Dr. Holmes' idea of the use of the tampon, I was negligent in this case, but I was fortunate enough to get firm uterine contraction and absolutely no postpartum bleeding. In the first case the placenta was separated probably during the labor. In the second case I am certain that the separation was accomplished long before the woman had gone into her labor and before I saw her. But in each case the retraction was quite firm, and the result, so far as the women were concerned, was all that could be wished for immediately following the delivery.

Dr. I. F. Harter, Stronghurst, Ill.: I was called last August in consultation with a confrère, who had been called to the case perhaps a week before. He had found the woman with some lancinating and irregular labor pains. This was her fourth pregnancy; the three previous ones had been normal and she was at this time about seven months advanced. At the time he was called in, she was somewhat anemic and he put her to bed. Along with the uterine tumor he observed a tumor about the right horn of the uterus and the right tube, which he thought, perhaps, was an ectopic pregnancy. As the time advanced the tumor increased in size and I was finally called in. From the shock from which the woman was suffering, I was convinced that there was concealed hemorrhage. The tumor was very large and conical-shaped in the right horn and tube. The woman was in poor financial circumstances, the husband a farm hand, and they were living under very unsanitary conditions. On the recommendation of Dr. J. F. Percy of Galesburg, we removed the patient to the Galesburg Hospital, where she could be constantly watched. She remained in about the same condition for about four or five days; then labor came on and she was delivered of a seven months' baby, and immediately following a large amount of blood and clots was expelled, which confirmed our diagnosis.

Dr. F. D. Marshall, Chicago: The patient whom I have in mind was seen in the fourth labor. On examination I found everything normal. The presentation was left occipito-anterior and with no indication of placenta prævia. Fifteen minutes after preparation had been made for the delivery, the patient had a profound hemorrhage. She then told me that she had had about an hour before a sharp pain in the left side up near the fundus. What had happened, was the query in my mind, to cause this premature separation of the placenta. She had been suffering for a number of days with a severe attack of bronchitis, with a cough so spasmodic that it was almost unbearable. I recognized that there was a partially detached placenta. There was little time to spare. I gave her a full dose of ergot. The membranes were ruptured and with the normal presentation the delivery was completed within fifteen or twenty minutes without resort to version, forceps delivery or anything of the kind. In this case the first examination gave no evidence of hemorrhage. The second examination showed that a very large quantity of blood had been discharged. If there had been any delay in the coming down of the head I should have performed podalic version and delivered in that manner. Promptness is the means by which most of these patients will be saved.

Dr. R. W. Holmes, Chicago: I have had three cases with characteristic developments of the accessory tumors. In one case the intern thought that it was a case of twins. I thought so until I inserted my hand and found a baby in one horn and an enormous blood clot in the other. I maintain that vaginal Cesarean section should never be done blindly. Any man who has had a case of ablatio placentæ with the large amount of blood escaping and obscuring the field of operation, knows that vaginal Cesarean section can not be done safely or well under such conditions. If there is no hemorrhage, a condition which, however, almost never occurs, vaginal Cesarean section is the scientific procedure.

THE DIURETIC ACTION OF ADRENALIN AND THE ACTIVE PRINCIPLE OF THE PITUITARY GLAND.*

E. M. HOUGHTON, Ph.C., M.D.,
AND
C. H. MERRILL, M.D.
DETROIT.

Many speculations have been indulged in by scientists to account for the physiologic function of the pituitary gland. This is especially true of the posterior or infundibular portion which in the human being is connected by a stalk with the tip of the infundibulum, and embryologically is to be regarded as an outgrowth from this part of the brain. This portion of the pituitary body, according to Berkeley, is very complex in its histologic structure; it contains many nerve cells, neuroglia tissue and a large quantity of glandular-like epithelial cells, which are so arranged as to form elongated vesicles or tubes, some of which contain a colloidal material. This structure suggests a secretory function.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Several writers have demonstrated by physiologic experiments that when extracts of this tissue are injected into the vein of anesthetized animals certain interesting changes occur in the circulatory system. Some of the earlier experiments were contradictory, but the experiments of Howell have often been confirmed by others and repeatedly by ourselves.

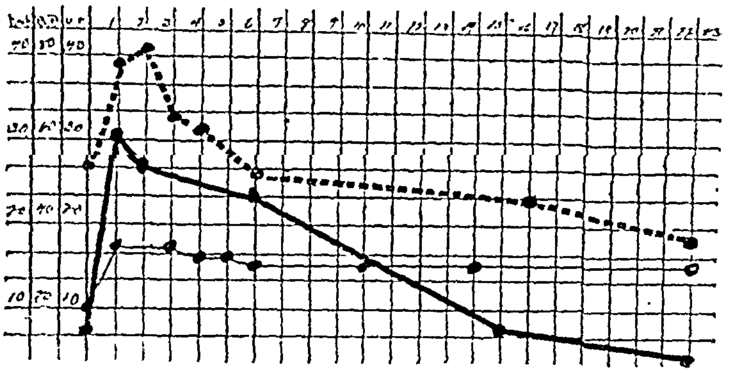

Fig. 1.—Chart showing results obtained from adrenalin. The figures in the three columns to the left indicate the respiratory rate, blood pressure in mm. Hg and urinary flow in drops, respectively. Dots indicate when observations were made. Broken line, blood pressure; light line, respiratory acceleration; heavy line, increase in ureteral flow.

The action produced is very similar to that following like administrations of adrenalin. The blood pressure is markedly raised chiefly by peripheral stricture. In the case of adrenalin this action is very transient, while with the pituitary material the blood pressure remains elevated much longer, in some cases a half hour or more. Howell points out the fact that repeated injections were followed by less and less rise of blood pressure until finally there was practically no response at all. This is well brought out in Figure 8. The pulse rate is slowed even when the vagi are cut or atropin has been administered, and the heart beats stronger than before.

For the experiments outlined in this paper we have employed an extract prepared by our colleague, Dr. T. B. Aldrich, using the method given in a paper read before the American Physiological Society, which he describes as follows:

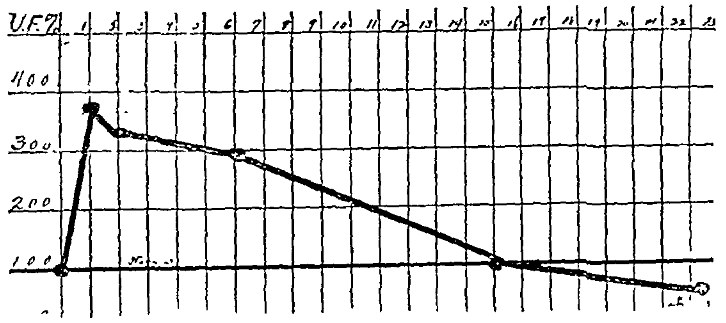

Fig. 2.—Chart showing average urinary curve for five dogs receiving .00001 gm. adrenalin in 5 c.c. saline solution and injected into the femoral vein. Figures at the left show percentage of increase of urinary flow. Figures at top indicate minutes.

PREPARATION OF EXTRACT OF INFUNDIBULAR BODY.

The infundibular portion of the pituitary body is carefully separated from the hypophysis cerebri and ground to a very fine pulp. To this, which constitutes about 8 per cent. of the weight of the moist gland, acidulated water (twelve times its weight) is added, and the mixture gradually heated to about 90 C. A portion of the proteid matter is coagulated by this procedure and removed by filtration. The remaining proteid, together with the phosphates, is removed for the most part with a solution of uranium acetate. The filtrate is practically without color and free from proteid. It represents the extract that has been used in the physiological experiments. One c.c. of such an extract, when injected intravenously into a dog, causes a rise of from 15 to 45 mm. of mercury and represents 0.1 gm. of moist infundibular body or 0.01 gm. of dry. Since there is considerable inorganic matter present, the active body in 1 c.c. must be much less than the above. I think I am safe in saying that the active substance in 1 c.c. of such an extract is not more than 1/32 of a grain. In all my experiments, extending over some months, in which thousands of glands have been used, I have found such extracts, for the most part, very uniform in their physiologic action when injected intravenously.

From this concentrated extract Aldrich also reported having obtained a crystalline picrate and a sulphate in solution, which were found extremely active in producing a rise in blood pressure. We have conducted extensive experiments which showed positively that this material is practically non-toxic when given internally or injected subcutaneously into guinea-pigs or rabbits or injected into the abdominal lymph sac of frogs.

The purpose of this paper, however, is to consider more especially the influence of the pituitary material on the secretion of urine. Professor Shafer in a recent paper makes the following statements:

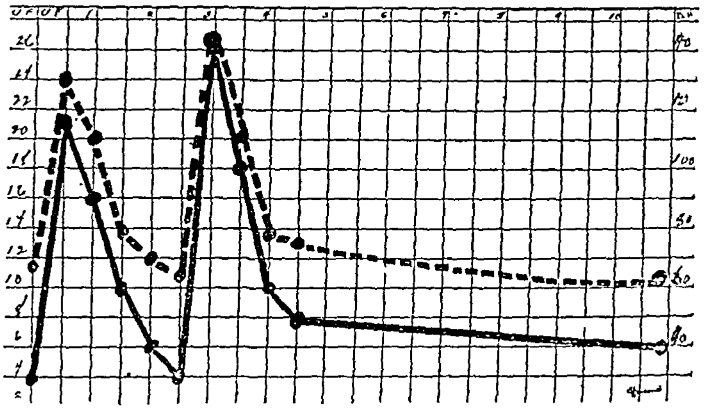

Fig. 3.—Chart showing that the increase in urinary flow (heavy line) follows very promptly on the repetition of the dose of adrenalin. The broken line indicates the blood pressure; the injections were made at 0 and at 2½.

INFLUENCE OF PITUITARY MATERIAL ON URINE SECRETION.

Pituitary extracts contain another hormone, the action of which is even more interesting than that which affects the heart and vessels. This second hormone has been found by Dr. Herring and myself to have a specific effect on the functions of the kidneys and to promote a free flow of urine—even if, as is often the case with animals under anesthesia, the urine may for a time have ceased to flow. Preceding or accompanying this increased flow of urine the kidneys expand, owing to the dilatation of the arterioles, so that the pituitary extract, while producing vascular constriction throughout the body generally, produces in the kidney vessels the opposite effect. This by itself must greatly assist the formation of urine.

But it is certain that, apart from the physical assistance to the formation (filtration) of urine derived from the increase of blood pressure and blood flow within the kidney, which it produces, pituitary extract also has a specific exciting effect on the cells which secrete the urine. In other words, although ordinarily accompanied and aided by a rise of general arterial pressure, due to general arterial constriction, and by expansion of the kidney vessels, due to local dilatation, the increased secretion of urine is essentially due to the glandular cells of the organ being stimulated to activity by the agency of a specific hormone.

This is proved by the fact that if a "repeat dose" of pituitary extract be given—which, as we have seen, is inactive so far as the rise of blood pressure is concerned—marked increase in the rate of flow of the urine can still be obtained. This may be accompanied by dilatation of kidney vessels, but, on the other hand, such dilatation may not occur at all—so that it is clear neither the kidney dilatation nor the rise of blood pressure are essential to the diuretic effect of pituitary extracts, which is due, therefore, to the presence of a special hormone. . . . That the internal secretion of the pituitary acts normally in promoting the functions of the kidneys there can be little doubt. This is, indeed, confirmed by the frequency with which polyuria is mentioned as a symptom in cases where the pituitary has, on postmortem examination, been found to be enlarged.

DETERMINATIVE EXPERIMENTS.

Three series of experiments were undertaken to determine if possible the reason for the diuretic action produced by the active substances of the infundibulum as reported by Shafer.

Observations were made on the excretion of urine by two normal individuals, care being taken during the periods of observation, which extended over several days, that the food, drink and habits and the periods of work, exercise, etc., should be the same. After the normal excretion of urine had been determined by careful observation, relatively large doses of the pituitary extract were given internally, with the result that, apparently, there was a slight increase in the amount of urine voided during the periods of observation, which corresponded to those of the normal. The results, however, were inadequate to establish the positive fact that the material produces any marked diuretic influence on persons in health. Observations were likewise attempted on dogs, but the results were even more irregular than those obtained in the experiments on human beings, so it was concluded necessary to make additional observations by more refined laboratory experiments. Owing to many interruptions, however, and absence from the laboratory on pressing matters, the experiments have not been as exhaustive in character as was at first intended; in fact, this report may be looked on as one of progress merely to be amplified and completed by subsequent work.

A series of dogs were anesthetized by morphin and chloretone. Cannulæ were placed in the ureters for measuring the outflow of urine from the kidneys, the individual drops being recorded on the kymograph (Fig. 4) through electric connection.[1] The carotid artery was connected with a mercury manometer so that records could be made directly on the drum of the kymograph (Fig. 4). The respiratory movements were also recorded on the kymograph (Fig. 4). The three connections were not made in all of the experiments, as it was deemed unnecessary.

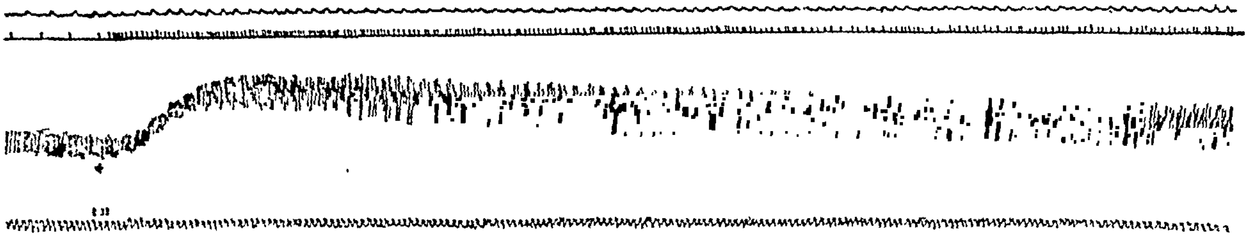

Fig. 4.—A typical kymographic tracing from which the analytical charts have been prepared. Top line, respiration; second line, water flow; third line, blood pressure; bottom line, time in seconds.

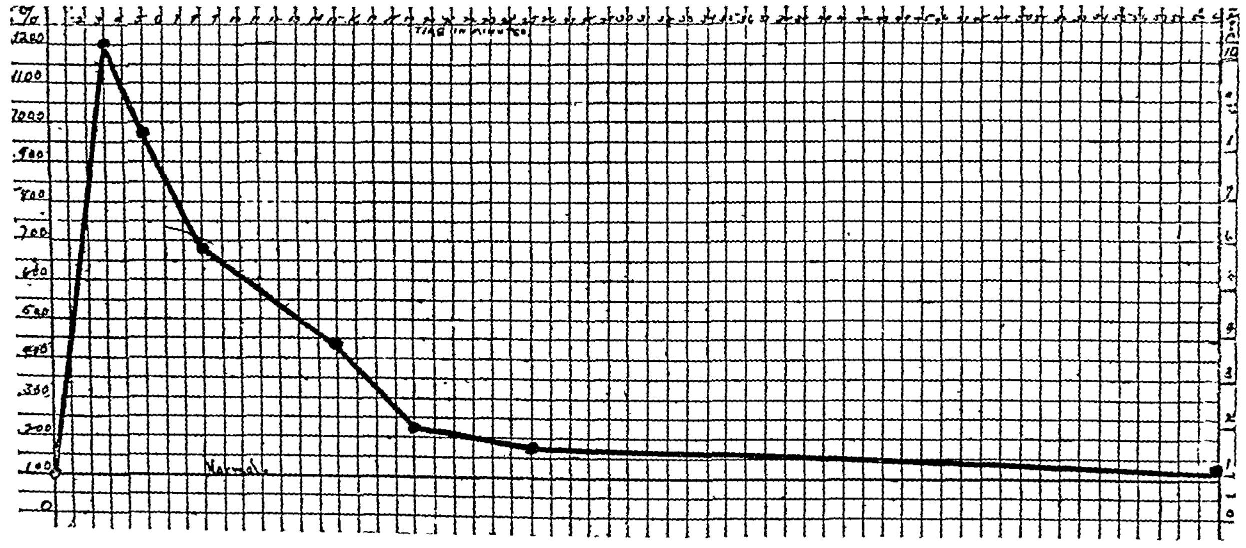

Fig. 5.—Chart showing the average urinary flow from five dogs receiving the pituitary extract in the vein. Figures at the left, percentage of increase; those at the top, time in minutes.

Reference to Figure 4 will show the manner of recording the experiments. The upper tracing is the record of the respiratory movements. It was intended only to register the number—not the character—of the respirations. Immediately below, a tracing records the drops of urine flowing from the ureteral cannula, each perpendicular stroke indicating a drop of urine. The next tracing below is the record from the carotid artery. At the bottom is the time record in seconds. Immediately above the actual time of the observation is recorded in numerals. The experiments showing the action of adrenalin and pituitary extract were carried out in precisely the same manner.

---

[1] See explanation accompanying the chart in Figure 4.

The chart in Figure 1 indicates in a characteristic way the results as obtained from adrenalin, being transferred from the kymograph sheet to the tracing cloth and the analytical data expressed in numerals. The three columns of figures at the left-hand side of the sheet indicate the respiratory rate, urinary flow in drops and blood pressure in millimeters of mercury, respectively. The figures at the top of the sheet indicate the time from the beginning of the experiment in minutes. The dots on the lines indicate the time at which observations were made. It will be observed that the blood pressure (broken line) rose very sharply from 56 to 88 millimeters of mercury, but within six minutes from the beginning of the experiment had fallen back to normal. This is characteristic of the blood-pressure action of adrenalin when administered intravenously. The light line indicates the respiratory acceleration. The heavy line shows the increase in ureteral flow from 8 minims per minute to 30 minims per minute, the maximum increase in flow corresponding fairly closely in time with the maximum blood pressure. The increase in urinary flow, however, continues for a much longer time than the increase in blood pressure, at the end of fifteen minutes the flow being approximately the same as at the beginning of the experiment.

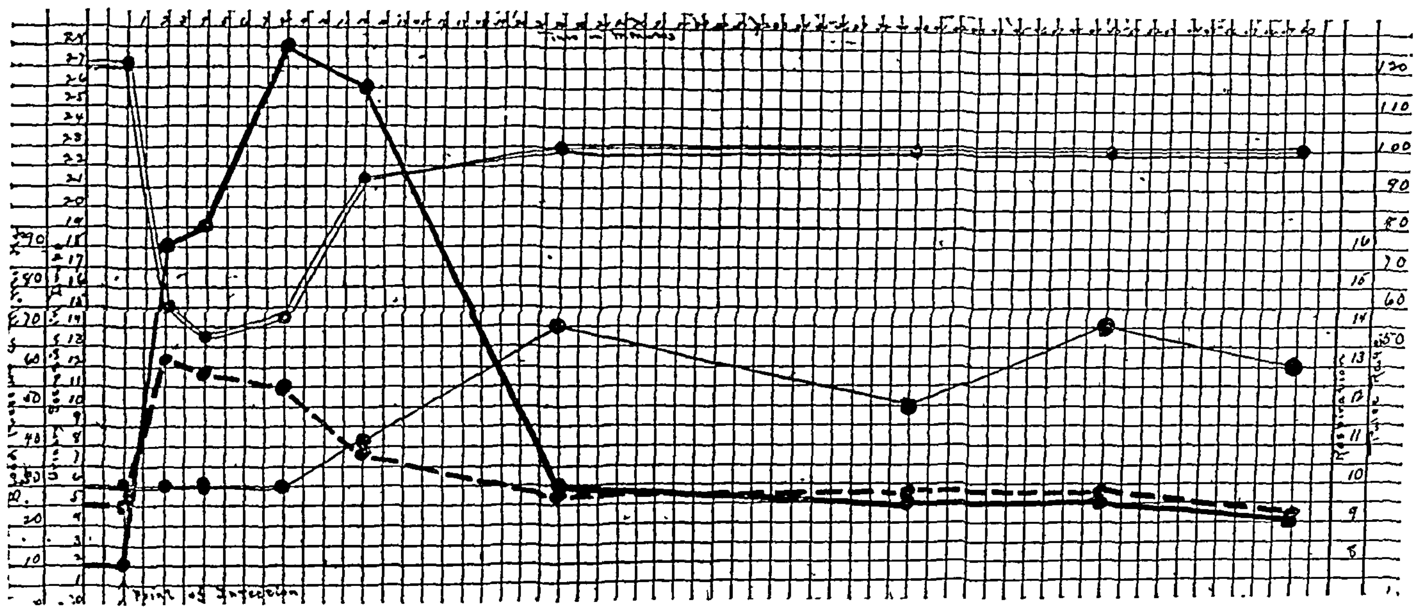

Fig. 6.—Chart showing the result of one experiment with pituitary extract on the respiration, blood pressure, pulse rate and urinary secretion of an anesthetized dog. The numerical values of the tracing are indicated at the right and left sides of the sheet. Heavy line, ureteral flow; broken line, blood pressure; light line, respiration; double line, pulse.

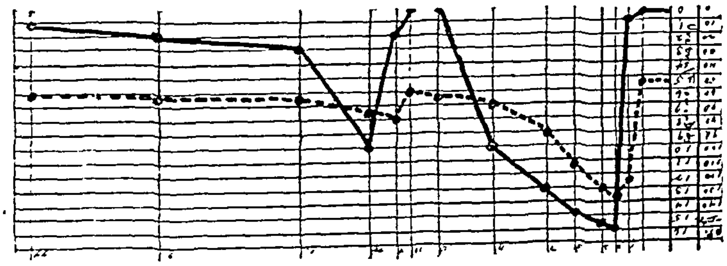

Fig. 7.—Chart showing the action of pituitary extract in repeated doses. Note that the blood pressure rises much less after the second injection, while the increase in urinary flow is very marked, but still less than after the primary injection. Heavy line, ureteral flow; broken line, blood pressure; injections at 0 and 17 mins.

The chart in Figure 2 shows the average urinary curve for five dogs receiving administrations of 1/100,000 of a gram of adrenalin dissolved in 5 c.c. of saline solution and injected into the femoral vein. The figures at the left-hand side of the sheet indicate the percentage of increase of the urinary flow, while the time from the *beginning of the experiment* in minutes is given at the top.

It will be observed from the charts in Figures 1 and 2 that the increase in the flow of urine corresponds quite closely to the rise in blood pressure but that the flow continues above normal for some minutes after the blood pressure has reached normal.

Experiments were undertaken after the technic of Sollmann[2] to determine the action of the pituitary extract on the secreting cells of the isolated kidney. Cannulas were placed in the renal vein and ureter and determinations made of the flow of blood from the cannula in the vein and the amount of urine secreted and flowing from the cannula in the ureter, record being kept from time to time. The kidneys were placed in a saline solution kept at body temperature; likewise, the fluid for perfusing the kidney was warmed beforehand; apparatus was arranged so that perfusion could be carried out at 50 and 100 mm. of mercury pressure; the experiments being undertaken to determine whether the pituitary extract had a specific influence on the secreting cells of the kidney or whether the increased flow of urine observed in animals receiving intravenous injections of pituitary extract was merely dependent on the increased blood pressure produced. The following tables will give the details of the experiments:

TABLE 1.

SHOWING EFFECT OF INTRAVENOUS INJECTION OF PITUITARY EXTRACT.

Time.	B.P. in mm. Hg.	Pulse per min.	Resp per min.	Urine, drops per min.

TABLE 2.

Time.	Ureteral Flow.	per Minute. in Minims
10:00	A. Kidney perfused with 1 per cent. saline at 50 mm. mercury pressure.	
10:01		14
10:03		14
10:06	4 minims per minute	10
10:21	B. Pressure raised to 100 mm. mercury.	
10:21	12 minims per minute	50
10:24	11 minims per minute	25
10:27	C. Pituitary extract, 1½ mg. to 0.0015 gms. per c.c. of saline. Pressure 100 mm. mercury.	
10:28	12 minims per minute	20
10:31	6 minims per minute	26
10:36	5 minims per minute	21
10:37	D. Blood pressure lowered to 50 mm. mercury.	
10:39	2 minims per minute	35
10:40	1 minim per minute	20
10:42	E. Saline, 1 per cent., used instead of pituitary extract solution.	
10:44	Zero	12
10:48	Zero	12
10:49	F. Pituitary extract added as before.	
10:51	Zero	12
10:58	Zero	8½
11:01	Zero	8½
11:05	G. Raised pressure to 100 mm. mercury.	
11:06	Zero	25
11:07	3 minims per minute	36
11:14	3 minims per minute	45
11:17	3 minims per minute	35
11:22	H. Pituitary extract withdrawn and 1 per cent. saline introduced.	
11:22	3 minims per minute	40
11:23	3 minims per minute	40
11:33	2 minims per minute	30
11:43	4 minims per minute	42
11:45	4½ minims per minute	46
12:44	I. Pituitary extract added as before.	
12:47	4 minims per minute	80
12:50	4 minims per minute	90
1:05	2 minims per minute	100
1:35	1 minim per minute	100
1:41	J. Saline, 1 per cent.	
1:55	1¼ minims per minute	96

TABLE 4.

Time.	Ureteral Flow.	Venous Flow in Minims per Minute.
10:20	A. Saline, 1 per cent., at 50 mm. mercury pressure. Perfusion of fresh kidney.	
10:23		6
10:27		5
10:32	1½ minims per minute	5
10:40	1½ minims per minute	6
10:45	1½ minims per minute	5½
	B. Raised to 100 mm. mercury pressure.	
10:46	6 minims per minute	75
11:00	1 1/5 minims per minute	15
11:05	1 1/5 minims per minute	..
	C. Lowered to 50 mm. mercury pressure.	
11:09		7½
11:25	1 minim per minute. (Flow very slow both sides.)	
11:33	D. Pituitary extract. 50 mm. pressure. (1 mg. to 3 c.c., 1 per cent. Saline.)	
11:35	1 1/5 minims per minute	..
11:40	1½ minims per minute	7
11:41	E. Raised to 100 mm. mercury pressure.	
11:42	4 minims per minute	15
11:45	5 minims per minute	15
11:54	5 minims per minute	15
11:55	F. Lowered to 50 mm. mercury pressure.	
11:56	2 minims per minute	6½
12:00	1¼ minims per minute	6
12:05	1 1/5 minims per minute	5

From these tables it will be observed that at 50 mm. mercury pressure a 1 per cent. physiologic salt solution produces but a slight flow of urine through the ureter. When the pressure is increased to 100 mm. mercury, both the urethral and venous flow is markedly increased. The same general fact is observed when pituitary extract is added to the saline perfusion, but the urethral and venous flow is less, both at 50 mm. of mercury and at 100 mm. of mercury than where saline alone is used.

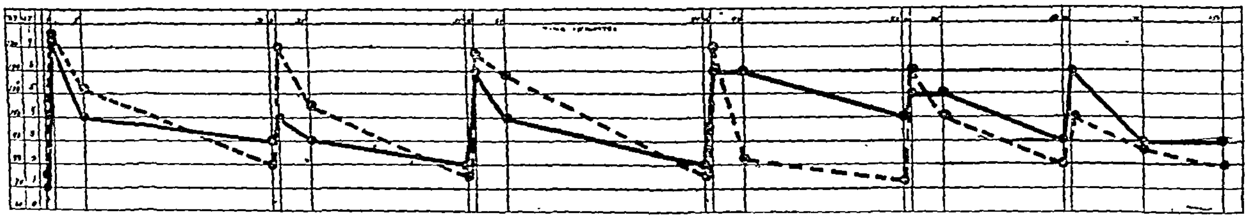

Fig. 8.—Chart showing the effect of repeated intravenous injections of pituitary extract on the blood-pressure and urinary secretion of anesthetized dogs. Heavy line, ureteral flow; broken line, blood-pressure; injections at 0, 31, 55, 85, 110, 130 minutes.

TABLE 3.

4:05	3¼ minims per minute	14
4:10	2¼ minims per minute	14
4:25	1½ minims per minute	12
4:26	C. Lowered to 50 mm. Mercury pressure.	
4:30	Practically blocked.	
4:35		2
4:38		1½
4:40	D. Pituitary extract at 50. mm. mercury pressure.	
4:45	1¼ minims per minute	1⅓
4:50	2 minims per minute	3
4:55	1⅓ minims per minute	5
5:00	E. Pituitary extract at 100 mm. mercury pressure.	
5:01	3 minims per minute	40
5:05	2½ minims per minute	50
5:10	2½ minims per minute	46

CONCLUSIONS.

From these experiments it would seem to us that the explanation of the increased urinary flow in anesthetized animals depends chiefly on the increase in blood pressure produced by the intravenous injection of the adrenalin solution or the pituitary extract in solution rather than on a specific action on the secreting cells of the kidney. It is possible, however, that a specific action on the kidneys occurs, but if so it is less marked than in the case of the 1 per cent. saline solution.

Macroscopic observation of the perfused kidney indicated that there was considerable enlargement of the organ while the experiments were being carried out. This would assist in the more rapid secretion of urine, especially if accompanied by increased pressure, but, as just stated, there is not the same degree of relaxation or dilatation of the blood vessels in the kidney as follows the perfusion with the saline itself. This is as we would expect, since experiments on the web of the frog, on the inflamed conjunctiva of the rabbit and other animals show positively that the pituitary extract does narrow the caliber of the arterioles.

If the pituitary extract possesses, as Shafer believes, the specific secretory effect, it would seem to us that it should manifest itself by greatly increased flow of urine when brought in contact with the secretory cells of the kidney. If it does have this specific action it has it to a much less degree than sodium chlorid itself.

THE TREATMENT OF TUBERCULOSIS BY THE ADMINISTRATION OF MERCURY

AT THE UNITED STATES NAVAL HOSPITAL, NEW FORT LYON, COLO.

BARTON LISLE WRIGHT, M.D.
Surgeon, United States Navy.
LAS ANIMAS, COLO.

COMPARISON OF TUBERCULOSIS AND SYPHILIS.

Both tuberculosis and syphilis are classed by pathologists among the infectious granulomata. The pathologic histology of the two diseases are so similar as to be almost identical. I venture to say that a microscopic diagnosis between a gumma and a tubercle is almost impossible in many instances unless the specific microorganism of one or the other disease be found in the tissue under examination.

In both diseases the pathologic lesions are represented by a round-cell infiltration of the affected tissues. In both cases the lesions may vary in size from that of a pin-head to a large mass or tumor.

Stengel's Pathology (1906) says of the tubercles (p. 278): "Tubercles tend to coalesce, forming larger tubercular masses, and sometimes distinct tuberculous tumors are so produced." Of gummata the same work says (p. 311): "The gumma presents itself as a nodular mass, varying in size from small tubercle-like formations (*miliary gummata*) to tumors the size of an orange or larger." In regard to the pathology of syphilis of the lungs, Stengel writes: "It has been the occasion of much dispute whether the many forms of disease attributed to this cause can be really so classified. Undoubtedly some of the conditions attributed to syphilis are cases of tuberculosis or of some other form of pulmonary disease."

Stengel writes of the Lustgarten bacillus as follows (the edition of 1906 is cited in all these quotations): "The attempts to find a specific cause for this disease (syphilis) have not as yet met with definite success. The organism which until very recently had the best claim to recognition is that observed by Lustgarten. This resembles the tubercle bacillus very closely." I shall refer to the Lustgarten bacillus later.

Tuberculosis is a chronic, infectious, granulomatous disease, characterized pathologically by a round-celled infiltration of the affected tissues or organs, and symptomatically by various symptoms common to all debilitating diseases which tend toward cachexia. If the word "syphilis" be substituted for "tuberculosis" in the above definition, the characterization seems to be accurate.

A study of the pathology of both diseases will show their close relationship from this standpoint. Their symptomatology, closely observed, does not reveal any wide differences except the early symptoms of syphilis (the chancre and early secondary lesions). This similarity is especially noticeable in the comparison of these diseases occurring in the same organs or tissues. In the late secondary or tertiary stages, without an absolute syphilitic history, unless the specific organism of one or the other disease be found, or one of the tuberculin tests be applied, a differential diagnosis is often impossible.

THE LUSTGARTEN BACILLUS.

From the present point of view it appears probable to me that the authentic cases of syphilis in which Lustgarten and others found his bacillus were complicated by tuberculosis; that the bacillus found in the lymph glands and channels, in the blood, and in the various organs were tubercle bacilli; and that the lesions in these organs or tissues were of mixed origin. That these organisms disappeared under mercury was, at that time, a strong argument that they were the bacilli of syphilis. During the six months in which we have treated tuberculosis at the naval hospital with mercury we have seen the tubercle bacillus rapidly diminish and disappear from the sputum. Since it is now definitely established that the *Treponema pallidum* is the specific cause of syphilis, it would appear probable that the disappearance of the Lustgarten bacillus under mercury in certain cases occurred because this drug had a pronounced antituberculous as well as antisyphilitic action.

The text-books on therapeutics teach that the administration of mercury is contraindicated in debilitating diseases tending toward a state of cachexia; yet for years we have treated syphilis with mercury, and I do not think any one will question that this disease occupies a prominent position in this class of diseases.

RESULTS OF TREATMENT.

During the past six months we have not found a single tuberculous patient whom mercury injured in the least; on the contrary, in over 85 per cent. of all the cases so treated an improvement has taken place, and in most instances this improvement was decidedly marked, not only from the point of general condition, but the diseased pulmonary area was greatly reduced. Nor has this improvement been confined to the diseased lung, for we have cured a number of patients with secondary tuberculous laryngitis, one with secondary tuberculous epididymitis and one with secondary tuberculosis of the kidney and prostate.

My attention was first drawn in the spring of 1905 to the antituberculous action of mercury. At that time I was on duty at the U. S. Naval Hospital, Pensacola, Fla., having a camp for the treatment of tuberculosis as an adjunct. We had several cases with a mixed infection of tuberculosis and syphilis, the latter disease being in the early secondary stage, with the characteristic skin eruption present on admission, and with a profuse mucopurulent expectoration, which in both instances contained numerous tubercle bacilli. Physical examination revealed extensive pulmonary involvement, and both were running high temperatures.

The patients were placed on mercury and both improved with astonishing rapidity. The temperatures soon fell to normal and the physical evidences of syphilis quickly disappeared. The patients gained weight rapidly, the tubercle bacilli in the sputum rapidly diminished, cough and expectoration were much lessened, and physical examination of the lungs revealed a remarkable improvement in the condition of these organs.

This led me to believe that mercury must have some pronounced antituberculous action. A study of the pathology and symptomatology of syphilis convinced me that this thought was not unreasonable.

I then placed about twelve tuberculous patients, whom I thought free from syphilis, on mixed treatment by mouth, obtaining excellent results in most instances.

About this time I was detached from duty at the hospital and ordered to sea, which prevented further work in this line.

In January, 1908, having been ordered to duty at the U. S. Naval Hospital, New Fort Lyon, Colo., I resumed the experiment, now giving mercury by deep muscular injections, in order to avoid the derangement of the gastrointestinal tract which had given my earlier patients considerable annoyance.

The results of this method of treatment were reported to the Surgeon-General, U. S. Navy, under date of March 1, 1908, and were published by the Bureau of Medicine and Surgery in the April number of the *United States Naval Medical Bulletin.*

A second and more elaborate report, submitted under date of May 25, 1908, appeared in the July number of the above magazine. In this paper I considered forty cases with 70 per cent. improved, in many of which the improvement was marked.

A third paper, under date of July 28, 1908, appeared in the *New York Medical Journal,* Aug. 29, 1908.

During the first quarter, ending March 31, 1908, our death rate was 11.29 per cent.; during the following quarter, ending June 30, the death rate was 4.76 per cent., or a reduction of 42 per cent. I think this great reduction in the death rate most significant. To my mind it clearly establishes the specific nature of mercury in relation to tuberculosis.

During the present quarter, ending September 30, we have had but one death, with a daily average of 105 patients, giving a death rate of 0.95 per cent., or a reduction in the death rate over the previous quarter of 80 per cent. and over that of the quarter ending March 31 of 91 per cent.

This would seem to be the best evidence that the reduction in the death rate during the second quarter was not accidental but entirely due to the administration of mercury. It emphasizes in a marked degree the antituberculous properties of the drug and strengthens my convictions as to its specific qualities, expressed in my second report.

These results appear all the more remarkable when we consider the fact that over 60 per cent. of the patients on admission are far advanced, in many of whom grave secondary involvements complicate the serious pulmonary lesions.

During the past five months all the deaths but one have been those of patients who have been in the hospital less than two months. Autopsy in all cases revealed extreme pulmonary involvement, secondary ulcerative tuberculosis of the intestinal tract and larynx and tuberculous involvement of many of the internal organs.

We began this treatment about seven months ago, and so far the results have been so exceedingly and uniformly good as to warrant us in regarding mercury as a strong antituberculous agent, if not a specific in this form of disease. We have now ten officers and fifty-seven enlisted men who have been on mercury for two or more months. Of the ten officers so treated all have improved, nine with remarkable rapidity. One failed for the first few months but is now improving.

Of the total number of patients under treatment, 86.5 per cent., or fifty-eight, have improved. Two of these have been cured, and in many of the others the improvement has been exceedingly marked.

Of the two cured one has been restored to duty and is serving on board the U. S. S. *West Virginia.* The other ceased taking mercury some two months ago, since which time he has been employed in the stables at this hospital. Up to August 2 his health had been excellent and he has maintained his weight of 169 pounds. Unfortunately, on the date named above, after several days of feeling ill, he was placed in bed with a diagnosis of typhoid fever, which has been confirmed, for we now have a small epidemic of this disease among our patients.

If this patient recovers, and this seems probable, it will be interesting to see whether or not it will relight his recently cured pulmonary tuberculosis.

Two officers, who are not included in the sixty-seven cases mentioned above but were among the first to avail themselves of this method of treatment, have returned to duty.

The first, discharged as cured on April 2, has since passed his examination for promotion to a lieutenancy and served as executive officer of a large receiving ship, which duty requires constant mental and physical execution. He is now at sea. His health is and has been excellent since his discharge from this hospital.

The second, who has had tuberculosis since 1898, left the hospital at his own request on June 13 with evidence of disease still remaining in both apices and a few tubercle bacilli present in his sputum. Since that time he has been on duty in Brooklyn, N. Y. I recently received a letter from him dated August 3, in which he states that he is enjoying excellent health and has held his weight of 180 pounds, in spite of the extreme hot weather and bad climatic conditions. He is keeping up the injections of mercury.

Of the remaining 13.5 per cent. of the sixty-seven patients considered, two have held their own, six have failed and one has died. The autopsy in this last case showed total involvement of both lungs, both of which were riddled with communicating cavities and the entire small intestine encircled with tuberculous ulceration, and the liver and spleen were both the seat of tuberculous disease.

Among the patients considered above we have had fifteen with secondary tuberculous laryngitis, ten of which were ulcerative and five infiltrative, all of which have been cured. These cases also embraced eight cases with cavity formation, in five of which improvement took place, while in two the cavities have been absolutely obliterated. Of the remaining three, two have failed and one died.

As is natural, of the sixty-seven patients treated with mercury eighteen are men at present confined in bed in the infirmary, where in most instances their serious condition required them to be placed on admission. These patients would ordinarily be regarded as hopeless, yet 50 per cent. of them are improving, and there is much more pronounced movement from the infirmary to the ambulant wards than the reverse.

The above results have been obtained under the most adverse circumstances, for the hospital is under process of construction and is being built up around the patients. We lack many of the conveniences and some of the necessities of a completed hospital and have been short of medical officers and nurses at all times. The officers who are patients have been quartered in old dwelling-houses built in the sixties, repaired to meet the emergency, but with slight provisions for out-door life, while the infirmary is the old post hospital built about the same time and but poorly adapted to its present use. Plans have already been prepared for new buildings for these purposes, and we hope that we shall soon have buildings of modern construction and design.

By contrasting the above results with those obtained by the patients who have refused the mercury treatment, but who have enjoyed every other advantage this hospital affords, viz.: rest, life in the open air, splendid climate, good and suitable food—in fact, all that the present condition of this hospital affords—the argument in favor of the administration of mercury is most clearly established.

Of all the patients who have passed through this hospital and have not taken mercury but 33 per cent. have improved, and in most of these the improvement has been more from the standpoint of general condition, as in but few cases has the pulmonary lesion been decreased in extent.

ACTION OF MERCURY.

We believe that mercury acts in two ways: first, as a tonic, increasing the vitality of the cellular elements of the various organs and tissues, and, second, in rendering the blood bactericidal, producing an antitoxin therein, which has a direct destructive action on the tubercle bacillus. This action of mercury is cumulative and lasting, and the immunity conferred by the early doses, plus the resistance to the disease developed by the increased cellular vitality, places the patient in such condition that as treatment is continued smaller doses of mercury are required to obtain the desired results.

If we continue to give the improving patient the same dose of mercury on which he was first placed and began to improve we shall sooner or later notice, first, a rise in temperature, and, second, a loss of weight. Should these signs be passed unnoticed, it is probable that more or less serious damage would result; possibly an active general cellular degeneration, including the cellular elements of the blood, would occur, resulting in more or less permanent damage to the patient, if not a rapid decline and death.

METHOD OF TREATMENT.

It is only by close observation of each individual patient that the original and succeeding dosage can be determined. The drug should never be pushed to the point of salivation.

Our experience with this method of treatment has shown us that the maximum dosage for the original series of injections can not be carried much beyond thirty injections without producing the conditions mentioned above, and that after a period of rest, on resuming the injections the dose carried through the second series of injections must be reduced.

Our routine, therefore, has been developed by experience as follows: One injection of hydrargyrum succinimidum gm. 0.013 (gr. 1/5) is given every other day until thirty injections have been given. Then injections are discontinued and potassium iodid gm. 0.2 (gr. iii) to gm. 0.648 (gr. x) is given, well diluted with water, one-half hour after meals for two weeks. Then potassium iodid is discontinued and no medication is given for one week. Injections are then resumed as follows: One injection every other day until thirty injections have been given, on alternating injection days giving hydrargyrum succinimidum gm. 0.013 (gr. 1/5) and gm. 0.006 (gr. 1/10) respectively. After the thirtieth injection the same course of potassium iodid is given as followed the first series of injections; then a week free from medication. The injections are then resumed again the succinimid gm. 0.006 (gr. 1/10) being given every other day until thirty injections have been given. By the end of this third series experience will direct any necessary further treatment. The above recommendation for dosage is not to be considered absolute, but only a guide. Close observation of each individual patient must fix the dose of the first series of injections.

At times the initial injection will produce a slight febrile reaction, after which the temperature should fall to what it was prior to the injection. Experience has taught us that if this drop does not occur, or if the rise in temperature occurs after the second injection, the dose administered was too large and should be reduced at once.

In conclusion, I desire to thank the staff of the hospital for their aid and support; the commanding officer, Medical Inspector C. T. Hibbett, U. S. N., for his encouragement, and Surgeon W. H. Bucher, U. S. N., whose long experience in the administration of mercury by deep muscular injections in the treatment of syphilis has made his advice and suggestions most valuable.

A NATIONAL DEPARTMENT OF PUBLIC HEALTH.

A MESSAGE TO THE PEOPLE ON ITS CHARACTER, STATUS AND ECONOMIC VALUE.*

CHARLES A. L. REED, M.D.
CINCINNATI.

The active interest long taken by the New York Academy of Medicine in the effort to get a stronger, more comprehensive and more definitely organized national public health administration at Washington makes it singularly appropriate that the present status of the movement and the character of probable proposals looking to that end shall be discussed in this presence. And in taking up that subject at this time I may say that I am conscious of several sources of satisfaction.

In the first place, the agitation long conducted by the distinguished body that I have the honor to address, by the American Medical Association and by other bodies of the organized medical profession, is at least bearing tangible fruit in influential cooperation on the part of the laity.

About two years ago a national public health defense league was organized in this city. A little later a movement originating in the American Association for the Advancement of Science resulted in the organization of an influential body known as the Committee of One Hundred. These two movements have since joined forces and, together with the American Medical Association, are keeping the question before the public and before Congress.

POLITICAL ACTION.

One of the practical results of their efforts was the adoption of a plank in the Ohio Republican platform of this year declaring in favor of "the organization of all existing national public health agencies into a single national public health department." The same declaration, in effect, was made later in the platform of both parties in various states, notably, I believe, in Connecticut. This was followed by declarations of similar purport in the national platforms of both the Republican and Democratic parties. I am gratified to be able to assure you that the President has been giving careful attention to this general question and that he has now authorized the statement to be made that he will formulate definite proposals and transmit them with his endorsement to Congress at its next session.

---

* A public address delivered under the auspices of the New York Academy of Medicine, New York, Oct. 29, 1908.

A CAMPAIGN FOR THE GENERAL WELFARE.

It now devolves, not only on the people themselves, but on the nearly 140,000 physicians of this country, as the natural custodians of the public health, collectively and severally, to bring the most active influence to bear, not only in seconding this salutary move on the part of the President when once he shall take the step, but to anticipate that action by a prompt, active and persistent campaign in behalf of this fundamental measure for the public welfare.

The lines on which this campaign ought to be conducted vary in different localities, but there are certain general features that ought not to be ignored in any locality. These features are suggested, in part at least, by the failure to pass the various measures that have heretofore been submitted to Congress. Here let me digress far enough to say that these failures are to be construed only as valuable and, for that matter, successful educational efforts in the general evolution of the desired legislation. Nearly every law that to-day stands the test of the courts is able to do so because it has had to stand the test of more or less prolonged opposition in Congress.

Mr. Sherman framed not less than six antitrust measures, all of which were successively defeated, before he finally fashioned the great law that to-day bears his name and that for eighteen years has stood the test of every judicial tribunal in the land. But, able statesman that he was, he both learned from and taught by each successive effort and so, I trust, have we learned from and taught by the experience that has befallen us in this great effort to furnish something like adequate protection to the greatest natural resource of this country—the health, lives and productive energy of the people themselves.

SOME CAUSES OF FAILURE.

And now, prompted by this spirit, we can, I think, discover several of the causes of failure actually to pass the measures heretofore submitted to Congress. In the first place, our attempts at actual legislation were premature in the sense that they preceded the actual education of the people and the consequent development of public sentiment on the subject. In the next place, it is now apparent that previous proposals have been too radical and have too generally been framed in contravention of the fact that most legislation must be built on previous legislation and is, therefore, essentially evolutional in character. And in the third place it is now very evident that the failure of the medical profession sooner to procure this legislation in behalf of the people is attributable in no small measure to the dearth of representatives of that profession in the legislative halls of the people. We may, with advantage, examine these several reasons somewhat in detail.

A POPULAR PROPAGANDA.

The dissemination by the medical profession of knowledge with respect to public health problems has not been as widespread or as effective as either our opportunities or the character of the subject would warrant. Much, indeed, has been done, and the present information of the people is almost entirely the result of the altruistic initiative of the physicians of this country. But too much of the work has been done in, and confined to, the medical societies and too much of the publicity has been done through and confined to the medical press.

This has too generally amounted to a mere carrying of coals from Newcastle to Newcastle and back again to Newcastle. What is demanded by the times is that proceedings such as these here this evening, and such as an international tuberculosis congress and such as the county medical society, whenever relating to general welfare subjects, shall be heralded through the popular prints until they carry their lesson to every home and fireside in the land. Carry the message to the people! This should be the motto of the campaign.

THE MESSAGE TO THE PEOPLE.

But what shall be the message? In the first place let us tell the people some things that have been done, that they may judge for themselves and, judging, hope for and help secure other things that can be done. In doing so it is not necessary to go so far back as Jenner and the discovery of vaccination and to tell them of the beneficent results of that first great achievement in preventive medicine. Nor is it essential that we should recount the great revelations of Pasteur that gave him that immortality which consists in a perpetual abiding-place in the grateful memory of man. Nor need we speak of Lister. These are oft-told tales that have come to tax the interest of the hearer. But we can tell them of some things of to-day. We can tell them of Finlay, and Reed, and Lazear, and Carroll, and how, from their martyrdom, it comes that the argosies of commerce can to-day sail the seas without flying the yellow flag of pestilence. Tell them this; tell them the humanity of it all.

But if that does not appeal to them, translate it into terms of dollars and cents and show them how "profitable" has been the "investment." Compute the commercial disaster contingent on a single visitation of yellow fever to our southern seaboard. And then tell them how the recent attempted invasion of this country by that dreadful disease was repelled and defeated through the efficiency of the service under Wyman. But, above all, tell them how the zone of pestilence at the Isthmus of Panama has been made the habitation of health that the waters of the two great oceans may be joined, all made possible by the great genius of Gorgas. Tell them that, right now, health and life are being made secure on our mainland and commerce itself, domestic and foreign, is being protected by a valiant guard stationed at our seaports—stationed, for instance, right here at New York—sifting out and thrusting back the disease that comes in the guise of the immigrant, and at San Francisco, where the triumphant battle against the bubonic plague has added new laurels to our country, and especially to our Public Health and Marine-Hospital Service. Tell them of our food and drug laws, and of our supervision of cattle intended for food supply. Tell them of the sanitary work that is being done right at their doors, work that makes their homes habitable. Then tell them that if these things are being done other things that ought to be done can be done.

THE GREAT WHITE PLAGUE.

What, then, are some of the things that are not done, but that ought to be and could be done with a properly constituted national health administration? The broad answer to this question is that preventable diseases could be still further prevented to the almost incalculable benefit of the people. And this, too, must be a part of the message to the people. Let us point to tuberculosis, in the campaign to combat which the scientists of the world have but recently been in congress at the capital of our country. This is a preventable disease, yet, as I pointed out at that congress, this disease, according to the statement of experts, kills 160,000 people and keeps in invalidism nearly 700,000 more people in this country every year.

This is a veritable warfare in which the American people, arrayed on one side, are to-day offering not so much as a passive resistance to an army of invasion—the army of the bacilli—already encamped in our midst, in our very homes, a host more numerous than all the men in all the armies and all the navies of all the countries of all the world in all the ages. And each individual in that host is capable, under favoring conditions, of destroying a human life. As a matter of fact, the human lives thus sacrificed each year in this country are equivalent to the enlisted men of both our army and navy. What if these two arms of our service were wiped out of existence in a single year by a foreign foe? Do you not suppose that every resource of our country would be taxed to repel the invader, to destroy the decimating minions of death? Or suppose that first Indianapolis, then Kansas City, then St. Paul were as suddenly wiped off the map. Would not the people's representatives in Congress vote, if necessary, the last dollar in the treasury to avert such a menace from still other cities?

POISONED WATER SUPPLY.

Now let us consider a condition to which I have been calling public attention for several years. I mean the prevalence of typhoid fever, due to the almost total lack of sanitary supervision over streams that are used in large part and that, in the immediate future, must be used in still larger part as sources of water supply. Many of these streams lie within the states and consequently come within the jurisdiction of the states. But others are distinctly interstate streams and as such fall within the jurisdiction of the United States government. As the protection of interstate streams from contamination will make it necessary similarly to control their tributaries, it may be necessary to expand the functions of the national government in this regard, from the control of interstate streams to the control of interstate watersheds.

This will be especially true in all instances in which the states fail to do their duty by protecting the streams within their borders from death-dealing contamination. But both intrastate streams and interstate streams are, with few exceptions, being rapidly converted into open sewers that disseminate disease. The exceptions are found chiefly in Massachusetts, New York and Pennsylvania. No other states of which I have knowledge have adequate laws on the subject, or, if they have such laws, they do not enforce them. In this regard they are no worse than the United States government, the Congress of which, in spite of executive recommendation, and in spite of the fact that it had a bill on this subject pending before it during the last session, failed absolutely to take any action for the correction of one of the most flagrant evils now afflicting the people.

THE HORRORS OF TYPHOID.

How flagrant is this evil? The first result of stream contamination is the dissemination of typhoid fever. "A thousand miles of river and a thousand miles of typhoid" is the characterization that I have applied with justice to conditions in the Ohio watershed. Most victims of typhoid fever get the disease by drinking the excrement of some other typhoid patient. Then they, in turn, in the absence of sanitary regulations, feed their own excrement to a lot of people further down stream. These facts are very generally known, yet there is popular apathy on the subject. The thought is disgusting, but, disgusting as it is, it does not seem to have impressed itself on Congress.

Nor does the fact that about 28,000 Americans die from this disease in a single year seem to have signified anything to the very Congress under whose authorization the statistics were gathered and promulgated. Yet if every man, woman and child in either Bloomington, Ill., or Lexington, Ky., or Fort Worth, Texas, had died of that disease in a single twelve months, the world would have stood for a moment in consternation—and then something would have been done. But the death roll is not the full measure of the calamity. Nearly 200,000 people were ill of typhoid, but recovered after an average invalidism of sixty days. This is equivalent to saying that every man, woman and child in Louisville, Ky., or Minneapolis, Minn., or Providence, R. I., was ill for two months.

SOME UNSOLVED PROBLEMS.

Now I have talked so far about some demonstrated certainties. We know, in these particulars, just what can be done and just how to do it. But there are in addition many unsolved problems of almost equal importance to the people. Over 60,000 people die annually from cancer, the actual cause of which science has so far failed to reveal. And the death rate from cancer is advancing by leaps and bounds. The prevention of pneumonia, from which 125,000 of our people die each year, is an unsolved problem. The cause and nature of rheumatism needs further elucidation. Science has not yet set a barrier against the prevalence of influenza, from which alone a million or so of people are made ill and are consequently deprived of their productive energy for more or less time each year, and from which cause alone something like 15,000 people die annually. Yet these are all obviously infections and, therefore, preventable diseases. The campaign against the carrier insects—against the flies and mosquitoes, for instance—both of which are responsible for the dissemination of disease—is already a demonstrated success on the Isthmus of Panama and simply awaits legal authorization and executive machinery to make it a success in the states.

There are dozens of other unsolved problems of equal scientific and economic importance. I have ceased talking about the humanity of it all. That argument does not reach the average man. I am simply insisting that, in the presence of all this demonstrated waste—actual and needless waste in dollars and cents—it is the obvious duty of the government to establish a department of public health with power and resources that will enable it to grapple with the great problems—the greatest of all really economic problems—to a few only of which I have alluded to-night.

SOME ASTONISHING FIGURES.

Now what does all this mean? I do not speak of the pain, the sorrow, the humanity or, rather, the inhumanity of it all. There are those who have feelings, are capable of sorrow and who realize the awful significance of the fact that preventable, emphatically preventable diseases, in the aggregate, kill an average of one person every two minutes. But I now appeal to the larger number who, I grieve to say, think only in terms of dollars and cents. So let us translate consumption and typhoid, malaria and pneumonia, cancer and plague into their equivalents, into the coin of the realm. But let us begin with a few primary postulates.

In the first place the most valuable natural resource of this country, fields, forests and mines, not excepted, is the productive energy of the people. In computing the worth of this resource a human life, rather than an acre, a lode or a tree, must be the basis of reckoning. What is it worth? Let us see.

A man's life is his capital. What he earns is the interest on his capital. Then suppose that a man works 300 days in a year at $1.25 a day, and that this money thus earned, $375 a year, represents 5 per cent. on his capital, which, on that basis, would amount to $7,500. Then multiply this by 160,000 for tuberculosis, and 30,000 for typhoid, and so on through the list, which foots up at about a quarter of a million, then add it all together—and you will only have begun. You are to add to this the loss of productive energy of something like 700,000 people constantly ill for a whole year from tuberculosis and nearly half that number ill for sixty days from typhoid, and so on through the list, at $1.25 a day for each one. Then, ignoring the fact that the lives of many are worth thousands and hundreds of thousands of dollars a year, exclude the non-producers —women, children and dependents—by dividing the result by two. Then, still to be on the safe side, divide the result again by two, and the remaining figure, if translated into the coin of the realm and placed in our national treasury, would not only pay for a properly equipped national department of public health, but would, in addition, pay the current expenses of the army and navy, duplicate our armament on the seas, fortify our coasts, deepen our internal waterways, and, in ten years, would pay for the Panama Canal and wipe out our national debt.

Put this in the message to the people.

EXISTING PUBLIC HEALTH AGENCIES.

Of course, such a consummation in all its completeness is entirely beyond hope of realization. The figures are presented only to reduce to approximate concrete terms the enormity of present conditions—conditions which we know could be largely bettered through proper governmental agencies. Let it not be assumed that we are to-day entirely without such agencies—agencies that have been and are to-day doing excellent work.

But they are inadequate and, considered as a whole, scattered and unorganized and to that degree and in consequence of that fact are inefficient. The Public Health and Marine-Hospital Service is under the Treasury Department and, absurd as it may seem, the Secretary of the Treasury is the chief health officer of the United States. The Bureau of Vital Statistics is under the Department of Commerce and Labor. The Bureau of Chemistry, charged with the enforcement of the National Food and Drugs Act, and the Bureau of Animal Industry, charged with protecting the people against diseased meats, are under the Department of Agriculture. The national eleemosynary institutions, all of them public health agencies, are in the so-called Department of the Interior. Of course, the health of the army and navy is looked after by services organized within those respective departments.

There is to-day no service whatever specially organized to fight the plague of tuberculosis. No governmental agency is entrusted with the sanitation of interstate streams and the consequent protection of the people from typhoid due to these media of communication. There are no national laboratories for the solution of the yet hidden mysteries of contagion and infection. Other specific activities, such, for instance, as a campaign against disease-carrying insects, are not provided for, while the scattered agencies that we do possess are given such an unfortunate status in our scheme of government as to compromise their educational value and practically to deprive them of moral force.

Put these facts, all of them, in the message to the people.

MORE MEDICAL MEN FOR CONGRESS.

These facts, together with an intelligent and sympathetic appreciation of the nature of a great national public health service, the importance of establishing it, and, after establishing it, of fostering and maintaining it on a basis of highest practical efficiency, comprise a part, but only a part, of the many reasons why the medical profession should be more largely represented in the halls of Congress. When it is recalled that in the Sixtieth Congress there are but four physicians in the house of representatives and one in the senate, and when it is remembered, by way of comparison, that there are forty physicians in the Senate and fifty-six in the Chamber of Deputies in France, it becomes apparent that, of the two republics, our country is not deriving the benefit it should derive from the medical profession in the way of legislation. This becomes all the more apparent when the fact is taken into consideration that the present Congress, like the preceding congresses, is largely made up in both branches of members of the legal profession.

I mention this fact in no sense of reproach to that learned and honorable profession whose genius has largely fashioned our institutions and given shape and form to our laws—a profession that ought always to be and doubtless always will be largely represented in our legislative bodies. But we have now fallen on times when social and economic questions are clamoring for solution, when ethical problems are to be solved. For the accomplishment of these tasks it is of highest importance that our legislative bodies should be strengthened by a membership embracing more farmers and laborers, more physicians and ministers and educators, more business men, all unhampered with alliances, all fresh from the ranks of the people, all at liberty to serve the people. Then it will be that Congress will do the things that we pray for here to-night.

Put this in the message to the people.

THE POWER OF THE GOVERNMENT—A COUNCIL OF STATES.

The right of the national government, under the "welfare" and "interstate commerce" clauses of the constitution, to do many of these things is unquestioned. Yet there are many things that might better be done by the states. But the laws in the different states are generally inadequate and, whether inadequate or not, their complete lack of uniformity renders it impossible for the states to cooperate in the solution of a problem which, like the one under discussion, is coextensive with all the states.

Like laws for like conditions is the first requisite for the control for any national necessity by state legislation. And like laws by the states will probably not be enacted to any great extent until, under the initiative of the national government, the states shall send delegates to a representative body, a sort of council of states, which shall meet as a legislature or as Congress meets, in a session or sessions long enough to accomplish satisfactory results, and whose object shall be to formulate standard bills on various subjects and send them back to the legislatures for enactment. In this way, and in this way alone, can the states move with anything like satisfactory rapidity in meeting the crying demand for like laws for like conditions not only in regard to great sanitary problems such as I have been discussing, but in regard to many other problems that concern the economic and social welfare of all the people. This step should be taken without delay, for, even at the best, considerable time must elapse before results from this means can be realized.

But, aside from the special proposition that we are here discussing, some such step as I have outlined is imperatively demanded to conserve the states in their present integrity.

Put that in the message to the people.

THE PRESENT DUTY OF THE NATIONAL GOVERNMENT.

But what shall be done by the national government? I am not authorized to speak for the proposals which the President now has in contemplation. I do not feel that I am anticipating them in the least when I say that there ought to be but little absolutely new legislation undertaken as an initial step. The first thing that ought to be done is to assemble all existing public health agencies and coordinate them under a single head, leaving each agency to continue its activities under existing laws, supplementary laws to be enacted as they are afterward indicated. These agencies could be grouped into a single department and the title of the department so changed as to give titular recognition to the service without multiplying cabinet officers, to which latter action there seem to be sound executive objections.

Thus, if it should be found to be wise to make the Bureau of Vital Statistics the nucleus for the aggregated service, the name of the department in which it is located could be changed to that of "Department of Commerce, Labor and Public Health." Or, if it shall be deemed expedient to select the Department of the Interior, the name of the department should be changed to that of "Department of Education and Public Health," which, unlike the present title, would mean and stand for something distinctive among our great national interests.

Be that as it may, I insist, in the name of the medical profession, in the name of science, in the name of humanity, that a great governmental agency to conserve, as this one proposes to conserve, more lives, more homes, more property, and more money, than any other single agency in the whole plan of government, shall be accorded a status fully befitting its dignity and its worth.

And let this be the message to the people.

THE EPILEPTIC INSTITUTE COMPANY.

ANOTHER[1] FRAUDULENT CONCERN AND ITS SUPPRESSION BY THE POSTOFFICE DEPARTMENT.

Among the pseudo-medical institutions that have been investigated and closed through fraud orders by the Postoffice Department was a Cincinnati concern known as the Epileptic Institute. The following is an abstract of the report on this concern by R. P. Goodwin, Assistant Attorney General to the Postmaster General. It is based on an investigation conducted by Inspector George W. Sorenson and others:

This business consists of a medical treatment by mail of the disease of epilepsy. One Otto Kalmus, a resident of Cincinnati, commenced the business in the spring of 1903, under the name of the Epileptic Institute, and so it continued until July, 1907, when he incorporated it under the name of the Epileptic Institute Company, he continuing as president and general manager and principal owner. As a private address for patients who, it was explained, might not care to have it known that they were corresponding with an epileptic institute, use has been made of the name of Dr. H. J. Luecke, a physician connected until recently with the institute. While not with the institute since last November, Mr. Pyle and Dr. Schoenling explained at the hearing that by agreement with Dr. Luecke his name has continued to be used, and that the institute still receives that mail addressed to him which is also directed to Box 99 in the Cincinnati postoffice.

Until lately, communication with epileptics was obtained through advertisements in newspapers, chiefly those circulating among Germans and other foreigners. One of these advertisements, taken from the Dec. 13, 1905, issue of the *Home and Farmers' Companion*, a German agricultural paper published at Milwaukee, Wis., was furnished the inspector by Mr. John Edel, father of a former patient of this concern, and when translated reads as follows:

A BOOK IN REGARD TO FITS SENT FREE.

The Epileptic Institute in Cincinnati will send perfectly free of all cost to every reader who writes for it a valuable German Doctor book, containing many pictures, treating of the causes and cure of fits. It sets forth how and in what manner this terrible disease can be cured with safety, lastingly and for one's whole life, through a treatment altogether new. It is worth its weight in gold. It costs nothing and is securely packed, and will be sent gratis and post free. Order at once. Address Epileptic Institute, Box 99, Cincinnati, Ohio.

HOW PATIENTS ARE SNARED.

More recently the practice has obtained of purchasing the names and addresses of epileptics from, as the inspector says, "Other concerns that have obtained all of the money possible from such unfortunates without effecting a cure," and then mailing circulars to such persons, urging them to take treatment from the institute. Names have been so purchased, the inspector reports Mr. Kalmus and Dr. Schoeling informed him, from one Dr. Town of Fond du Lac, Wis., and from the firm The Guild Company of New York, N. Y. Mr. Kalmus identified for the inspector the circulars so sent by him to such persons soliciting the addressees to become patients of his institute. Samples of these circulars are among the papers. They are filled with extravagant and highly colored representations with reference to the unprecedented success of the institute's treatment, which it denominates the "Schönka" treatment, as a cure for epilepsy; and among other things it is represented that this treatment is original with the institute, and by its means the institute can successfully treat the heretofore-considered incurable disease, epilepsy, and in many cases effect a cure; that the treatment is something not known to medical science and is different from anything used by the profession in such cases; that the physicians of the institute are skilled and experienced specialists, and include "one of the foremost examining specialists in America." and that the case of each patient will be carefully considered, and in instances where a cure is not believed to be probable the patient will be so informed frankly, and also that the treatment is perfectly harmless.

---

[1] Previous articles in this series were: "The Reinhardt Case Concluded: The End of a Long Fight for the Protection of the Public Against Imposition," October 3, page 1144; and "Medical Institutes: How They Entrap the Unwary Young—the Hibbard Case as an Illustration," October17, page 1330.

The first circular sent to prospective patients is accompanied by a booklet entitled "Causes and Cure of Epilepsy, by Otto Kalmus, Epileptic Institute, Cincinnati, Ohio, U. S. A., Copyright 1905 by Otto Kalmus. All Rights Reserved." and also by a symptom blank on which the prospective patient is requested to outline his condition and return it to the institute. This symptom blank, when so returned, is the basis of the institute's diagnosis of the case. Quoting from this circular booklet and symptom blank, such statements as the following are held forth as inducements for those afflicted with epilepsy to commence treatment with this institute:

> It gives us pleasure to acquaint you with the efficacy of our treatment for Epilepsy and its related afflictions. We are specialists confining our practice to the treatment of these derangements; ordinary physicians cannot cure these diseases and frankly admit it when honest with their patients.
>
> Years of untiring research and investigation of a great number of epileptic cases have at last resulted in [illegible] ul method, originated by us and known as the [illegible] T.
>
> This treatment is not a general thing; [illegible] ed to all patients alike; the best results are obtained only when it is graduated to meet the special requirements of each case and directed at the predisposing cause.
>
> No matter how hopeless the case may seem, no matter how many doctors and remedies have been tried in vain, do not hesitate to consult us. If we regard the case beyond our power we shall not hesitate to tell you so. Awaiting return of the symptoms blank filled out and assuring you prompt and careful attention, we remain,
>
> x x x
>
> Specialists in the treatment of Epilepsy, Neurasthenia and disorders of the nervous system.
>
> Our treatment will be directed at the cause of the derangement. It is a mild and safe, yet radically effective method of treatment, and by adapting it to the individuality of the case we can offer the strongest possible encouragement.
>
> *The Schönka Treatment.*
>
> This treatment, known as the Schönka Treatment, is not the discovery of a day. It is founded upon the study, discovery and scientific research that have come down through centuries of medical investigation and learning.
>
> While this treatment will perform its part in assisting nature to effect a cure better than any other treatment, it must be admitted that not every case is curable. It is safe to state, however, that no other method has been more successful in the treatment of this terrible disease than the Schönka Treatment.
>
> No epileptic, no matter how severe his trouble, should hesitate in taking the Schönka Treatment, for if his case is curable this treatment is the one he can depend on.
>
> It is safe to say that no other method of treatment of Epilepsy has a greater number of cures to its record. There is no reason why anyone should continue to suffer from epilepsy or permit a dear friend or relative to suffer from this most annoying disease, when the means of relief are so near at hand.

Considerable of the booklet is also given up to distressing accounts of epileptic seizures in public: the obvious object being thereby to frighten the epileptic into exaggerating the consequences of his own affliction and purchasing the treatment.

The questions asked by the symptom blank are quoted below in full, to show the meagerness of the information asked for and the basis for the evidence, hereafter referred to, that it is insufficient to enable a doctor to make an accurate and scientific diagnosis of the condition of the patient:

Name of patient.
Give full address.
Express office.
Age. Weight. Complexion.
Married. Any children?
Occupation.
How long have you had epilepsy?
Original cause?
Have you any other disease?
Ever masturbated?
Any of your relatives afflicted with Epilepsy?
Have parents been subject to alcoholism?
How often do attacks occur?
Day or night?
How long do they last?
Do you lose consciousness completely?
Do you lose control of the bladder or bowels?
What symptoms do you notice before attacks?
And afterwards?
Is your memory impaired?
Do you have headache?
Any heart trouble?
How is your appetite?
Is your digestion good?
Bowels regular or constipated?
How many pints of urine do you pass in 24 hours?
Is it light or dark in color?
Do you suffer from incontinence of urine?
Sleep well? Are you nervous? Anemic?
Any difficulty in breathing?
Have you ever had an operation?
Do you use tobacco or strong drink?

For Females Only.

At what age did you menstruation appear?
Is it regular scanty profuse painful?
Have your monthly changes any influence on the attacks?
Any ovarian trouble? Displacement of the uterus? Or other female complaint?

Should the person to whom this first letter should be sent fail to return the symptom blank, the practice is to send him or her a second circular, further urging the epileptic to return the symptom blank, and impressing on him or her the unparalleled success that the institute is having in treating this disease.

Should the epileptic still fail to reply, it is the practice of the institute to send him a third circular of much the same nature as the second. In this circular occurs this statement:

> You secure without cost the opinion on your case of one of the foremost examining specialists in America.

Should the epileptic still fail to reply, a further circular is sent him of much the same nature as the preceding, in which is the following statement:

> It is a common enough thing to hear of those who are called incurable among sufferers from epilepsy; in fact if we believe what the ordinary doctor says, most epileptics, if not all, are hopeless and beyond human help. This is an error. Medical science has long been powerless, but we have progressed and modern science has found a way by which some cases of epilepsy can really be cured.

HOW PATIENTS ARE TREATED.

If in consequence of any of these circulars the epileptic should return the symptom blank, it is the practice to mail him a circular, reading as follows:

> My Dear ———
>
> Your letter with description of your ——— case arrived with this morning's mail.
>
> This case appears to be serious and somewhat complicated and demands most careful attention. Before giving you a definite opinion I desire more time in order to give the case the very best personal attention possible. I shall make an accurate diagnosis and notify you whether a cure can be effected.
>
> I greatly regret this delay but if you desire an exhaustive examination, it is absolutely necessary. You will realize that it is for your own interest and I believe I owe my success to the careful attention I give to each patient.
>
> Remember that I am considering the case and that you will hear from me in about two days, as soon as I have thoroughly investigated every symptom of the complaint.
>
> Faithfully yours,
> THE EPILEPTIC INSTITUTE CO.,
> Per Medical Director.
>
> P. S.—If you have not received our booklet explaining CAUSES and CURE of EPILEPSY, please notify me so that I may send you a second copy free.

Two days after the above circular is mailed, the practice, as Mr. Kalmus explained to the inspector, is to mail the epileptic the following circular as a diagnosis:

> My Dear ———
>
> Since writing you a few days ago I have given your case earnest, careful and conscientious study.
>
> I find that your spells and seizures are of Reflex Origin; you are suffering from what is called in medical language "——— Epilepsy," which is a deviation from the more common form of the disease and with which it is so easily confounded. Although there has been no perceptible change in your condition for some time, the chances are that unless prompt and energetic treatment is begun, the trouble will become further complicated and may result in the gradual loss of the more important functions of your brain and spinal cord.
>
> Whatever your experience has been in the past, I believe I am justified in saying that medicines have done more harm than good, for the reason that they were intended to smother and suppress rather than help *cure* the disease.
>
> It is a well-known fact that many brother physicians find it difficult to relieve Epilepsy when confronted with a stubborn case, and it is a constant source of astonishment to them, that I am treating some of the severest cases with great success. You see there are no less than forty-eight different types of Epilepsy; in each of these forms the attacks originate differently, consequently every type requires a modified system of treatment, which again must be varied according to the existing complications, and you will easily understand why a regular physician who in his entire professional career encounters at most not more than a dozen cases, can not possibly be qualified to treat such cases like a specialist, who comes in contact with almost every type daily.
>
> I have studied your symptoms carefully, studying out each separately and collectively, with regard to the progress of your disease and relation to your future health and I have also compared them with those of a number of similar cases of Epilepsy to see what results have been accomplished, so that I am able to tell you whether or not I can conscientiously offer you any encouragement.
>
> After this thorough investigation and diagnosis, I can now honestly say that your case should readily *yield to my treatment*, if commenced at an early date and my advice closely followed. In a case so deep seated and complicated, ordinary treatment would be of no avail: it would be useless to merely try to suppress and diminish your attacks: the special features must be considered and treatment skillfully directed at the *cause of the disease* if it can be reached.

It is therefore my intention to treat not your symptoms alone, but I shall endeavor to eradicate every *trace*, manifestation and effect of the disease entirely from your system, thus preventing a return of the attacks. My long experience in cases of this character has proven this the only successful way.

Because of the complicated nature of your *trouble*, some special remedies have been required in order to bring about quick relief, and the treatment which I have formulated for you is composed of different remedies, each *having its own object* to accomplish in restoring you to health. The medicines I prescribe for my patients are in my opinion, positively the best that medical science has *garnered from the wisdom of ages and are perfectly harmless*; they are mild, soothing and healing, contain nothing *injurious and leave* no unpleasant after effects. They are made with the greatest care and with strictest attention to such details as accuracy, purity and reliability. *I do not use opium, Hemlock or other dangerous drugs* that merely smother the symptoms and for a time ward off the attacks. *That is* one way of treating epilepsy, but it is not my way.

In view of the fact that in your case there exists a marked tendency for the worst and inasmuch as I presume you desire relief, I have *personally prepared* this treatment for you, which is absolutely accurate, and perfectly adapted in every particular to the requirements of your case.

I do not desire to appear as unduly urgent in the matter, nor do I approve of *sending medicine* C. O. D., *yet knowing* what your trouble can lead to if neglected, I thought it best to put this treatment within your reach at once, and I have lost no time and shipped *this complete course of treatment to your* express office, where the agent will deliver it to you on receipt of $.... and express charges.

This may at first seem high to you, but when you stop to consider that the treatment consists of the very purest and highest grade of ingredients that can be procured in any part of the world, also the time and painstaking care which I have given to their exact preparation for your especial case, *then I feel confident that you will come to the conclusion that it is just as* cheap as I could make it consistently with my high reputation, which I could not afford to jeopardize with a cheap grade *of remedies that would not produce* the desired results. I trust you will appreciate this conscientious work and the deep personal interest which moves me to do the very best that lies within my power for you and that I have in preparing this treatment taken the same care that I would were you my nearest kin.

Everything is securely packed and free from observation. Full, simple and explicit *directions*, regulations for your diet, mode of living, etc., are enclosed in the package. Read them carefully, pay attention to the treatment and I assure you that in a short time the unmistakable *signs of a marked change for the better should* become manifest. With proper care and attention, good results are generally accomplished, where the treatment is promptly taken. *I shall want you to write me freely, that I may know how you are* progressing and counsel you until no longer in need of medical advice.

I have tried to point out to you as *clearly as possible*, the wise course *to take and* I can urge you with good conscience to take this important step and begin your treatment as soon as you can, for should you let this opportunity go by, it might be a source of regret as *long as you live.* Above all things let me appeal to that strongest of human instincts, nature's first law—self-preservation. Do your duty by yourself.

On the other hand, I want your case for treatment, knowing as I do what a splendid thing it would be for you to be rid of that demon epilepsy—how much better, livelier and brighter you would feel and how much more life would be worth living.

I *do not accept any case unless I have the necessary time to* devote to any one so afflicted, and for this reason there has been a little delay in fully replying to your letters, but in future your letters will be answered on the same day that I receive them.

As soon as the medicines are received, will you kindly date and return the enclosed post-card, that I may make a note of the time the treatment began, on my books.

With best wishes, I remain,

Sincerely your physician,
The Epileptic Institute Co., Inc.,
per Medical Director.

(A copy of the Booklet, "GUIDE FOR EPILEPTICS" is enclosed in *package*).

P. S.—The package is shipped as coming from my Secretary, O. Kalmus. No one through whose *hands it may* pass will know what it contains, or that it comes from a doctor. I do this to protect you from annoyance as I find that many of my patients wish to avoid publicity.

This diagnosis letter is a stock circular printed in similitude of typewriting, and when sent out as a diagnosis to patients is the same in all instances, with the exception of the name of the prospective patient, the particular variety of epilepsy from which he is diagnosed to be suffering, and the price of the medicine. So far as the inspector could find, the practice has been to send out this stock diagnosis letter in all instances. At the hearing, however, it was claimed, that in some instances, which it was admitted were few, a special letter was prepared, and that sometimes cases were rejected, in which event, of course, the diagnosis letter would not be sent. When the inspector called on the institute to furnish him with the names of rejected cases, Mr. Kalmus produced the names and addresses of five persons. As to the four who resided in the United States, the inspector addressed inquiries to their postmasters. In three cases the postmasters knew nothing about the parties, and in the *one* case where the postmaster could locate the patient he discovered the case had not been rejected, but had in fact been accepted and medicines been sent to the patient C.O.D. and the price later reduced to induce acceptance of the package. The inspector also had a practicing physician of Cincinnati make up a fictitious case of an incurable case of hereditary epilepsy, which he then mailed to the institute. In return he received in due course the regular stock diagnosis. The institute's failure to furnish any real cases of rejected patients and its acceptance of the inspector's test of an incurable case indicate that the occasion must be quite rare when the stock diagnosis letter quoted above is not used urging the epileptic to apply to the institution for treatment and holding before him strong encouragement for a cure.

At the same time that the above diagnosis is mailed there is sent to the epileptic by express a package of medicine, with the charges to be collected on delivery.

Should the prospective patient decline to immediately accept and pay for the C.O.D. package, the institute mails him or her a regular series of letters to induce the acceptance of the package. In one letter it is said that "these remedies are not cheap compounds, but a scientific treatment skillfully prepared at a great expenditure of time and trouble from rare and costly medicines, and under my personal supervision solely for this case"; that "what you want is a cure, and my experience tells, that a system like my own, aiming at permanency of results is really the one worthy of your attention. These so much-needed medicines are now within your reach and it rests entirely with you to decide. If you wait it may be forever too late; but if you do your part promptly, I do not hesitate to predict a grand success"; that "you know the sad consequences of delay and I honestly believe there is no such thing as fail in this case." In another of this series of letters the epileptic is told that the institute's previous experience in curing just such cases convinces it that its treatment faithfully used will prove for him, as it has for so many others, "a genuine success." Reduction of the price of the C.O.D. charge is also resorted to to induce the acceptance and commencement of the treatment. Likewise, after the treatment has once been commenced the institute has a regular series of letters to mail the patient to induce him to continue with the treatment. One of the statements made in this series of letters is: "I am entirely satisfied that the treatment which I have shipped will prove its worth and merit, and just now is the very best opportunity to take it, for if there is no further complication, a cure should certainly be effected within a reasonable length of time."

The time that this institute urges its patients to continue with the treatment is from a year to a year and a half, and longer, varying, of course, in different cases. Its charge for medicine ranges from about $3 to $9 a month, the variance depending, it seems, on the amount which the patient can be induced to pay.

WHAT THE SCHÖNKA TREATMENT IS.

The medical treatment is so glowingly advertised by this institute as a "cure" for epilepsy is based on the bromids. It is what is generally known as the bromid treatment except—and this is where the institute rests its claims for unusual and peculiar efficacy—that the drug adonis vernalis is used in conjunction with the bromids. In connection with the medical treatment, the usual and ordinary rules regarding diet, hygiene, etc., are also given.

Dr. Kebler informs me that what is in general known as the bromid treatment is in common use by the profession in treating epilepsy; that its physiologic action has been quite well defined; *that it is not a "cure"* for the disease, but acts simply as a sedative, and in this way tends to suppress the attacks; that medical science to-day has no drug treatment that will cure this disease; that this disease is among the most difficult and intractable of all diseases to treat, and that small per cent. of the more favorable cases *only* have been successfully treated, and that the success *in* these instances has been due most probably to the *condition of the patient* himself rather than to the medication.

[The report then goes on to quote from the *text-book* or other writings of a number of recognized *medical* authorities, statements showing the evil results *that may* follow the long-continued use of the bromids. For instance, H. A.

Hare ("Text-Book of Practical Therapeutics," 8th edi., Phila., 1900, p. 110) says:

> In other cases, evidence of mental aberration develops, the patient becoming irritable, morose, and even homicidal. Sometimes, however, we find melancholia and hallucinations, and, rarely, exalted ideas. In still others a dangerous suffocative bronchitis develops, the patient may become profoundly cachectic, or the condition may resemble typhoid fever.

Testimony to the same effect is quoted from the works of Drs. Roberts, Bartholow, S. O. L. Potter, Sir T. L. Brunton, H. C. Wood, Sr. and Jr., Edward N. Clarke, G. F. Butler, J. B. Yeo and R. W. Wilcox. Dr. W. T. Spratling, an authority on epilepsy and for many years superintendent of the Craig Colony for Epileptics, at Sonyea, N. Y., a state institution of recognized merit, is also quoted at great length. From his remarks the following are selected:

> The colony has ascertained through the analysis of nearly thirty of the more widely advertised patent nostrums for the "sure cure" of epilepsy that the bromid is the base of them all.
>
> Many of these quack remedies so glowingly set forth in the public prints, possess the power of suppressing the attack for a time, but it is suppression only, not cure, and the patients are always worse afterward.
>
> If pushed too far, death may supervene from acute bromid poisoning. This happened in the case of a boy of 12 years, whom I knew, whose parents gave him too frequent doses of a patent nostrum, the essential ingredient of which, as with the bulk of patent epileptic cures, was bromid of potassium
>
> It is a frequent experience to see patients brutalized by bromid, go months without fits, but with a loss of mental and physical activity.

The report further publishes the replies to a series of questions, made by several of the more prominent practicing physicians in response to a request by Dr. Kebler at the instigation of the assistant attorney general. On all points the replies are practically unanimous, and are to the effect that symptom blanks sent through the mail can alone not afford data for a reliable diagnosis of epilepsy; that the indiscriminate use of bromids is dangerous; that the bromid treatment is not a cure, but only a palliative, for epilepsy; that the respondents have no personal experience of a single case in which a cure of epilepsy could be attributed to the use of the bromids alone; that adonis vernalis can be beneficial at best in selected cases of certain types only; that its use is liable to be attended with danger; and that they know of no instance in which a cure of epilepsy could be attributed to its use.]

ADONIS VERNALIS: HOW IT CAME TO BE USED.

As regards the drug, adonis vernalis, which the institute claims is what gives its treatment the peculiar and unusual merit that is claimed for it, and makes it a "cure" where science has been unable to discover any curative medication for this disease, in addition to the statements of the physicians quoted above, Dr. Kebler advises me that this drug has been known to and used by the medical profession for some years as a heart stimulant, and was for a while experimented with somewhat in connection with bromids for the treatment of epilepsy, but was found to be without value, except possibly in a few cases where there is an affliction of the heart which might be contributory to the case. He states, however, that such cases could only be recognized by careful personal examination. Dr. Schoenling told me that the use of this drug was suggested by Mr. Kalmus when it was proposed to undertake this scheme; that he advised Mr. Kalmus that he did not believe it was of value; but that Mr. Kalmus insisted, and they therefore experimented with it and found it to be of value, and so made it a part of the treatment. He did not tell me what experiments were made or on whom, nor was anything given me on this point except Dr. Schoenling's general statement. Mr. Kalmus is not a physician, nor has he a medical education; and Dr. Schoenling could not advise me how it was that Mr. Kalmus got the idea of using this drug in this connection. I am unable to understand how it was that this drug was made a part of this treatment, except that it was to provide a point for argument in the event, which may have been foreseen, that the unusual claims of the institute for the new and wonderful cure for epilepsy, when in fact the bromids were to be the base of the treatment, should be challenged.

INADEQUACY OF THE SYMPTOM BLANK.

The blank used by the institute to secure the patient's symptoms for diagnosing his condition and preparing his treatment has been set forth above. In addition to the statements of the physicians quoted above, Dr. Kebler advises me that he does not consider it practicable by such a means and such information for a physician to make an accurate and scientific diagnosis; and Dr. Schoenling also was forced to admit that such was not practicable in all cases, although he claimed that such instances would be few. The meagerness of this blank, as a basis for an accurate and scientific diagnosis, is quite marked when it is compared with that used by the Craig Colony above referred to in considering applications for admission to that colony (see "Bulletin" of April 1, 1906). As the institute's treatment is supposed to be predicated on the information so obtained, if it is insufficient for a proper conception of the patient's condition, the good faith with which such cases are undertaken to be "cured" must certainly be questionable.

THE RESULTS OF THE TREATMENT.

With the papers in this case is correspondence had by the inspector with a number of persons who were patients of this institute. The inspector says he procured their names and addresses in 1905, and that after allowing the 12 to 18 months to elapse in which the company claims its treatment will effect a cure, he inquired of them the results of the treatment. Not one of the answers received says that a cure was effected. A number state they obtained while taking the treatment more or less relief in the suppression of the attacks or the reduction of their severity or frequency. In some instances the patient became so bad from the effects of the bromid that the treatment had to be discontinued and the patient confined in a state institution. The suppression of attacks or the reduction of their severity or frequency, which this correspondence indicates is a result of this treatment, is, I am informed by Dr. Kebler, the ordinary effect of bromids. This result, however, does not mean that the patient has been cured of the disease.

HOW TESTIMONIALS ARE OBTAINED AND THEIR VALUE.

As part of the advertising literature of the institute to secure patients, use has been made of what seemed to be reprints of letters written by patients to the institute speaking favorably of the results obtained in the cases of the writers. The inspector wrote to the postmasters of all of the persons whose testimonials were so used. The correspondence, which is among the papers in the case, discloses that practically all the testimonials, some twenty in number, were directly or indirectly solicited, probably while the patient was still taking the treatment and was under the favorable influence of the bromids. In one instance the patient was given free treatment for his testimonial, and in another instance a present of a silver watch was used as an inducement for the giving of the testimonial. The correspondence developed that the persons giving these testimonials had not been permanently cured of epilepsy, though in most instances the attacks were suppressed or their frequency or severity reduced while taking the treatment by the effect of the bromids. The postmasters also indicate in several instances that it is not certain whether the patient was actually afflicted with epilepsy or was suffering merely from hysteria. This institute, it would seem, although knowing that these testimonials were the product merely of the ordinary effect of the bromids, nevertheless circulated them for the purpose of misleading and deceiving the class of persons from whom it solicited business into believing them actual cases of cures effected by some new and wonderful treatment. As heretofore stated, this institute appeals for business principally among foreigners, and the letters of patients that have been submitted on the hearing indicate that as a rule the writers are persons of small education and experience and are of a class that probably could be easily deceived.

WHO AND WHAT THE "SKILLED SPECIALISTS" ARE.

One of the strong reasons urged for taking treatment by this institute on those persons whom it solicits to become its patients, is the representation that its patients have the benefit and advantage of having their cases handled by trained and skilled specialists, including one of the foremost examining specialists in America. As I am advised, there have been connected with this institute, since it commenced business in the spring of 1903, three physicians, namely, Dr. E. H. Schoenling, Dr. H. J. Leucke and Dr. A. L. Guertin. Dr. Schoenling stated at the hearing that for about the first six months, being half owner for the first three months, he attended to the medical end of the business for Mr. Kalmus, examining the symptom blank and diagnosing the case, prescribing the treatment and compounding it as well; that after he then left, Dr. Leucke did this work until December, 1907; and that since then he has again done the diagnosing and prescribing and Dr. Guertin has done the compounding. Dr. Schoenling graduated in 1900, when about 22 years of age, has made no special study of epilepsy, except in connection with this mail-order business, is not a member of any medical society, is not regarded in the profession as a specialist, and has most of the time since his graduation worked for $25 a week for a Dr. Charles Shafer of Cincinnati, who advertises in the public prints soliciting kidney and urinary and sexual cases. The salary paid him for his work at the institute, he says, has been less than $100 a month; and stated that he spent but a few hours each day at the institute and regarded it as a sort of a side line to his regular work with Dr. Shafer. Dr. Leucke graduated in 1901, went to this institute in 1903, has had no special preparation in epilepsy, does not consider himself a specialist, and was paid by the institute, the inspector says, only $15 a month. He is not a member of any medical society, his professional standing is doubtful, his regular practice is sexual and urinary diseases, and in December last his advertisements were excluded from the Cincinnati papers on the ground that they related to the sale of abortifacients and the performing of criminal operation in violation of the statutes of the United States. Dr. Guertin receives $35 a month for his services from the institute, works there but a few hours each day, is not a member of any medical society, his standing in the profession is questionable, he has little or no practice in Cincinnati, and was investigated by this department in 1905 for giving to a concern against which was pending a charge of fraud under these statutes, and against which a fraud order was later issued, a testimonial as to its medicine, which he later admitted to the department was done for a valuable consideration, and without reading the statement which he was paid to sign, and which he repudiated as untrue. He admits he is not a specialist. These are the self-styled specialists and "foremost examining specialists of America" of this institute. No comment is needed on these facts to show the utter falsity and fraudulency of the representations in question.

A "FRANK" OPINION.

Another representation used to secure patients is that in those instances where a cure is not believed to be probable, the party will be so informed frankly. The evidence heretofore referred to as regards the inability of the institute to sustain its claims as to the rejection of incurable cases, and the test case of the inspector in which the institute solicited with its regular stock diagnosis circular, holding forth strong encouragement for a complete cure, what Dr. Lewis of Cincinnati referred to above, and, Dr. Kebler states, represents an incurable case of hereditary epilepsy, prove, it seems to me, that this promise is not made in good faith or with the intention of observing it.

On the hearing it was ingeniously urged for the institute, in excuse of this course of action, that it could not be told with certainty in advance of treatment what would be the result in any specific case. The natural question, then, is, Why is such a promise made? And the argument also obviously involves an impeachment by the institute itself of the good faith of the assurances of an almost certain "cure" with which it induces patients to undertake the treatment.

HARMLESS MEDICINES.

Another of the representations is that the medicines used are "perfectly harmless" and "contain nothing injurious and leave no unpleasant after-effects." The dangerous nature of the medicines that are used has been previously shown; and it is to be remembered that this danger is increased by the fact that the treatment is administered without the personal examination or supervision of a physician. The jeopardy to the health, and even reason and life themselves, of the patients that is involved in the methods used by this institute renders this business, it seems to me, one of the more pernicious and reprehensible of the schemes to make money by fraud which infests the mails and against which the statutes here in question are directed.

COSTLY MEDICINES.

Another representation is that the medicines used are costly and rare. Dr. Kebler advises me that none of the drugs which the institute states it uses can be said to be costly or rare.

THE BASIS OF TREATMENT.

Another statement is that the treatment is "directed at the predisposing cause," that "it would be useless to merely try to suppress and diminish the attacks; the special features must be considered and treatment skillfully directed at the cause of the disease," etc. In fact, as shown by the treatment actually administered, the very thing is done that it is claimed will not be done, and the thing which it is claimed will be done is not done.

The institute has submitted on this hearing as proof that it uses a treatment that is effective and of benefit to its patients, a considerable number of letters and affidavits of persons who state they took treatment from this institute and were benefited to a greater or less extent by the suppression of the attacks or the reduction of their frequency or severity, and a few even think they have been cured. In some instances it is stated that the patients realize that a cure is uncertain, but that they are satisfied with what results they are experiencing and are willing to continue longer with the treatment. These statements are to be taken in connection with all the other circumstances of the case, especially the facts as to the treatment which is administered, the mode in which it is done, and the qualifications and experience of the physicians handling the cases. When it is known what is the medication that has been given these people, namely, the bromid treatment, the physiologic effect of which is well known to medical science, the significance of these statements is easily appreciated. Nothing is disclosed except the well-known effects of the bromids, namely, that as a sedative they tend to suppress the attacks. One fact to be borne in mind concerning these statements is that they were prepared by the institute and its attorney to meet the charges here presented, and then sent to the patients to subscribe to what was written if they would; also that the statements seem to be principally from patients who commenced more or less recently taking the treatment and were still taking it.

The institute has treated in all, I am informed, about 6,000 persons. The probability is that it has carefully scanned its records and with the 100 or so cases which it has submitted to me to consider has put forward its better foot. The institute has given these people certain drugs with certain known qualities, and it would be strange indeed if some of them did not experience the ordinary effect of such treatment and feel satisfied therewith. But it must be remembered that each of these persons whose statements are presented, as well as the other patients of the institute the results of the treatment in whose cases are not disclosed, were all solicited and urged to pay their money and take this treatment with strong encouragement for a complete and permanent cure, and with the assurance that they would be treated with a new treatment originated by this institute and unknown to the medical profession generally, and which had the power to work cures in cases where the profession was helpless, and with the further assurance that they would not be drugged "merely to smother symptoms and for a time ward off the attacks—that is one way of treating epilepsy, but it is not my way"; also that their cases would not be accepted unless it was felt they would be cured; also, that the physicians of the institute were specialists and included the foremost examining specialists of America; also, that the treatment was entirely harmless, as well as many other statements to which attention has been called. In fact, the institute had no warrant for its strong encouragement to the prospective patient, to expect a complete and permanent cure, and could not have offered such hopes in good faith; it did not have any new treatment, but simply proposed to use a treatment based on the bromids, which are not a "cure" for the disease: it was intended simply to smother the symptoms, and was not intended to use some other way so fondly distinguished from the "smothering" process; it was not proposed to frankly so advise those persons who it was not believed could be cured, but it was intended to urge the treatment on practically every one without discrimination: and the physicians of the institute were not specialists as pretended, nor did the staff of the institute include the foremost examining specialists of America; but, in truth, the physicians of the institute were young graduates and men without standing in their profession and following questionable lines of practice, and were men employed at what would seem to be about as small salaries as any at which the required service could be obtained; and the treatment intended to be administered was not entirely harmless, but was of a nature that might wreck the health and even reason and life themselves of the patient. Therefore, while in what may be said to be a comparatively few instances, as the institute has not disclosed its records in the great number of its cases, patients have experienced from the treatment what is the ordinary effect of the bromids and may feel satisfied with so much, yet I feel it is not true that the other and the greater share of the patrons of the institute have not been deliberately deluded with false hopes and representations, and defrauded of their money which they probably would not have paid if aware of the facts, in addition to having their health, reason and life endangered. The answer to the claim that certain of the patrons are satisfied with what benefit they do get from the treatment, is that in that event were the business conducted with an honest purpose there should be no occasion for promising anything more. The satisfaction of the few is not justification for the defrauding of the many. Furthermore, this scarcely is the case in which the patients are sufficiently familiar with the facts to be able to determine whether they should be satisfied or not, and this is especially so of the patient who has commenced the treatment but comparatively recently, and particularly among the class of people among whom it appears the most of the business of the institute is solicited.

CRIMINAL PROSECUTION INSTITUTED.

After the fraud order had been issued against this concern, its promotor, Otto Kalmus, at once attempted to evade the effects of the order by starting the same scheme under another name—the Hamilton Dispensary. That his operations under the new title were extensive is evident from the fact that we received letters and "diagnosis blanks" sent out by this rechristened fraud from even as far away as the Philippine Islands.

The postoffice authorities again took up the matter and not only was a fraud order against the Epileptic Institute Company extended to cover the mail addressed to the Hamilton Company, but criminal proceedings were instituted against Kalmus. We learn from S. T. McPherson of Cincinnati, United States District Attorney, that Kalmus was convicted October 22 of using the mails in furtherance of a scheme to defraud. A motion for a new trial was made, which the court has under advisement. Meantime the defendant is out on $1,500 bail.

It is earnestly to be desired that the outcome of the case will be such that Mr. Kalmus, after enjoying a well-deserved rest at the expense of the United States, will go into a more honorable business than that of preying on epileptics.

A Proprietary Booze Miracle.—A brewery advertises an alleged malt liquor as a tonic, and makes the astounding statement, *apropos* of the thin man, whom it urges to take a glass with his meals, that "it will send red blood through his veins." Remarkable!

Clinical Notes

TREATMENT OF TRAUMATIC RUPTURE OF THE URETHRA.*

REXWALD BROWN, M.D.
SANTA BARBARA, CALIF.

Following severe traumatic rupture of the urethra, posterior to the peno-scrotal junction, unless immediate treatment be instituted, a grave condition presents, appalling even to the medical attendant. Tissues adjacent to and even far removed, relatively speaking, from the severed urethral ends become edematous and blackened, filled with extravasating blood and urine.

Death confronts the patient if exit is not found at once for the retained and decomposing urine. The physician realizes this all too well, and in his haste to find passageway for the locked-up waters he inserts into the urethra the rubber or metal catheter and attempts to force the same into the bladder.

Nor, perhaps, is the physician to be blamed for undertaking this seemingly logical maneuver. There is in text-books devoted to genito-urinary surgery a lack of clear detail concerning the management of this serious injury, and in nearly all to which I have access the wording of the paragraphs on the treatment is such that catheterization is given prominent attention—in some it is even recommended. This is decidedly wrong, and the inferences from such teaching have undoubtedly in the past been responsible for deaths.

The following rule should be universally observed: Whenever there is good reason to suspect, or there is known positively to be, a rupture of the urethra, a catheter or sound under no circumstances should be introduced into the urethra as a diagnostic or as a therapeutic measure.

There is a reason for this; nor is it that false passages may be produced through the edematous and infiltrated tissue. This accident, always possible in this condition, is serious in itself. The more important reason, however, is that the passage of a catheter subjects the injured tissues to the insult of infection, and infection in this devitalized area can in a few short hours easily turn the patient's chances from a practically certain recovery under proper treatment to the edge of death.

Why does cellulitis here so speedily depress the scales? Because the infection is under constantly increasing tension; the extravasating urine and blood and rapidly forming pus find no runways to the surface from the confines of the slowly yielding layers of fascia and skin. Tissue destruction and septic thrombus formation in the venous plexuses are very rapid, and toxic absorption increases proportionately with the tension. Toxemia, pyemia, septicemia, may, therefore, be the result of the passing of a catheter when traumatic rupture of the urethra is present.

But it will be said that the passing of a sterile catheter under the most aseptic precautions can not possibly be responsible for so disastrous a train of consequences. Yet it can—the trauma inflicted by the passage of a catheter along the urethra increases the virulence of, or makes virulent, the micro-organisms which have their habitat in the urethra. Among these are diphtheria bacilli, streptobacilli, and even streptococci. They are carried along to the area of laceration. What inviting pastures

LUMBAR APPENDICECTOMY.*

CHARLES G. LEVISON, M.D.
President of the San Francisco County Medical Society, 1908; Chief of the Surgical Service of the San Francisco Polyclinic; Visiting Surgeon to the Mount Zion, California, Women's and City and County Hospitals.
SAN FRANCISCO.

The following paper was suggested to me by Legeu's contribution[1] on "Lumbar Appendicectomy." This article referred to the removal of the appendix in the course of an operation on the kidney, such as Edebohls[2] has already advocated, while the operation about to be described was performed for the purpose of reaching an appendix acutely inflamed, which had been diagnosed as being in the retrocecal position.

When the abdomen is opened during an attack of acute appendicitis, it is not infrequent that the search *for the affected organ is futile. As this is not a new or* a unique experience to many operators, it is my belief that, in cases such as these, the appendix might be discovered if sufficient care were taken to determine its position previous to operation.

Localization can not be accomplished unless the so-called "McBurney's point" be ignored to a certain degree, because involvement of the appendix can be diagnosed by means of this point only when the appendix is found within this area.

ILLUSTRATIVE CASES.

A case which bears out the above statement occurred in my experience recently. An operation on a young woman revealed a gangrenous appendix situated in the pelvis. The necrotic organ had produced an abscess with consequent bowel obstruction. The case presented many of the signs of an acute appendicitis, but, as McBurney's point was not painful, the diagnosis of appendicitis was not made by the attending physician. As the point of tenderness was low, occupying the brim of the pelvis, and as the examination per vaginam revealed some thickening too high up to be tubal, I made the diagnosis of appendicitis. This was confirmed at operation. The incision at the operation was made quite low. The appendix was consequently found with much greater ease than would have been the case had the abdominal wall been incised in the usual position.

The condition which first attracted my attention to this subject occurred in the following case:

Patient.—An individual who had never been sick prior to his present illness, at which time he was seized with a violent abdominal pain. He was given a cathartic and on the following day was fairly comfortable; temperature 100.6; pulse 90. On the day following he was not ill but there was some abdominal tenderness on pressure. He was brought into the hospital the following morning by his family physician, with a temperature of 102.4; pulse 96. He had no pain on movement, but had some tenderness to pressure.

Examination.—I saw the patient at 3 o'clock in the afternoon; temperature 102; pulse 100; leucocytes 18,000, 80 per cent. of which were polynuclear. When questioned as to whether he had pain he answered that he had none. He had no pain on movement, and was able to turn in bed without discomfort. Abdominal examination revealed no tenderness whatever at McBurney's point or in the right iliac region. Deep pressure made in the region of the anterior superior spine (lumbar region) caused the patient considerable pain; at this point there was marked rigidity. Dulness in the right flank corresponded to a continuation of the mid-axillary line. The dulness, while it was not continuous with the liver dulness, occupied the right lumbar region almost completely. The tympany of the colon could be elicited so that the dulness was tympanitically dull, not absolute. There was no jaundice present.

Diagnosis.—The diagnosis of retrocolic appendix was made to the exclusion of gall-bladder condition; as the urine was normal, a perinephritic abscess was ruled out. This conclusion was reached in consideration of the tympanitic area between the dulness and the liver, despite the fact that the appendix region did not appear to be involved.

Operation.—An incision four inches long was made two finger-breadths above the crest of the ilium extending to one inch in front of the anterior spine. The gridiron operation was performed with more difficulty than is experienced in front on account of the thick bellies of the abdominal muscles which were encountered. There was no trace of exudate or fluid found within the abdomen when the peritoneal cavity was *opened. Palpation of the colon, in front and behind, did not* reveal the presence of the appendix and it was only by strong retraction of the colon forward that its posterior surface was exposed and with it a gangrenous appendix which extended from the anterior superior spine to the under surface of the liver. The appendix was gangrenous from its base to its extreme tip; there was no induration and nothing to indicate the presence of the appendix, which would never have been discovered if it had not been exposed to direct view. It was removed by ligation.

Postoperative History.—Convalescence was without particular incident with the exception of the formation of a fecal fistula, which closed within three weeks.

That the localization of the appendix is not easy of accomplishment and that it is open to error was shown by the history of the following case, which came under my observation during the same week that the previous case was observed:

Patient.—A woman who had never been sick was taken ill the day before with severe abdominal pain. She gave no history of gallstone disease. The conjunctivæ were slightly icteric. The physician in charge reported a slight dulness in the flank and some tenderness on pressure in the iliac region; temperature 101; pulse 100.

Examination.—The day following the patient was brought into the hospital with a temperature of 101.2 and a leucocyte count of 30,000, of which 90 per cent. were polynuclear. Dulness extended quite up to the liver and down to the crest of the ilium, filling the right flank. Here tenderness to pressure was pronounced. There was no trouble in the region of McBurney.

Diagnosis.—With the experience of the previous case it was felt that a similar condition was present but gall-bladder disease could not be ruled out because of the icterus and on account of the dulness which extended upwards and was continuous with the liver dulness. The existing jaundice should have attracted more of our attention to the gall bladder than it really did, but in view of our previous experience, a diagnosis of retrocolic appendix was made with due consideration of gall-bladder disease. The gall bladder was not seriously considered, as the anatomic situation of the dulness was not that of the gall bladder but was well away from the costal angle.

Operation.—Lumbar operation for a retrocecal appendix was performed, but at the upper end of the incision a distended gall bladder was seen. The incision was closed at once and the abdomen was opened by a right rectus incision. A large, thick distended gall bladder was exposed. The ducts, which were covered with exudate, were adherent to the intestines. The gall bladder was full of stones. It also contained a partially decolorized fluid. The operation was performed in the way usual for acute cholecystitis.

Convalescence from the operation was *uneventful.*

The history of this case is quoted for the purpose of showing how difficult at times the diagnosis becomes when this localization is attempted. It is believed, how-

[2] Ann. Surg., 1902, p. 137.

ever, that if the jaundice had been more seriously considered, the process would have been recognized.

RECAPITULATION.

The rule to be observed in the surgery of the appendix is, to make the incision correspond to the position of this organ. It can frequently be localized if the situation of the exudate and the rigidity are kept in mind.

When the exudate is situated in the loin, a diagnosis of a retrocecal appendix should be made, excluding, as far as possible, perinephritic abscess and gall-bladder disease. If low down, the differentiation from pelvic disease should be made. Naturally the classic form must first be thought of.

On looking over the literature, I find that this subject, strange to say, has been almost entirely overlooked.

About thirteen years ago, at a time when it was considered good surgery to hunt for the appendix, despite the condition of the patient, my practice was to discontinue the search as soon as I realized that this could not be properly and successfully accomplished. Largely through the influence of J. B. Murphy, this practice has now been adopted, so that to-day it is an accepted principle that this search should be discontinued under the conditions indicated. It is my conviction that, in those cases in which the appendix is not discovered, the offending organ is situated in the retrocecal space. With the appendix in this position and the abscess incised in the usual manner, either through the Lennander or McBurney incision, the pus is evacuated, but the appendix is not discovered because it is practically extraperitoneal. On several occasions in my experience, when the appendix has not been found at the operation and when a recurrence has taken place, the diseased appendix at operation, in each instance, has been found in the retrocecal position and then only after a long and tedious search. I fancy similar experiences have occurred to many surgeons.

CASES PROBABLY MYCOTIC, BUT NOT EVIDENTLY DUE TO BLASTOMYCES.

M. B. HUTCHINS, M.D.
ATLANTA, GA.

Case 1.—*Patient.*—Male, aged 51. He had a rounded nodule in the middle of his right cheek three or four years before the date of the examination referred to below. I saw him once at this time. Later he was subjected to various escharotic treatments. When he returned to me he brought from a competent pathologist the *simple diagnosis* of "cancer." Within a short time I requested that he get the pathologist to make another examination microscopically. This was refused because the latter believed his original diagnosis correct.

Examination.—January, 1902. The disease occupied an area from the right zygoma over the lower one-third of right *cheek and chin*, as well as slightly below inferior maxillary border and a little under the ear. The unbroken parts were livid, swollen, the surface partially cicatricial, partially open and irregular. In the raw surface and in the borders were pits from the size of the finger-tip to real subcutaneous cavities from which could be removed a most offensive white granular substance, like fresh butter grains, and pus. The odor was that of intensely sour buttermilk, which permeated the office for an hour after the removal of the dressings. There were no fine verrucous growths but some fleshy papillomata. The pus and white substance eventually burrowed in the subcutaneous tissues of the right temporal region over an inch. There was no carcinomatous hardness and no metastasis to glands. The striking features of this case were the white granules in the pits and cavities, the intense *secondary* pus infection, and the offensive sour buttermilk odor. Microscopic examination of granules and pus in caustic potash solution showed structures resembling fat cells from which the oil had been dissolved.

Treatment.—X-rays were employed for the greater part of a year, with some benefit, but there was final extension of the trouble. Iodid of potassium, even in large doses, had little, if any, favorable effect.

Clinical Course.—The patient was finally reported ill of pneumonia. I did not see him. He possibly died of extension of the disease to the right lung. Cultures could not be made and further microscopic examination was not to be had. There was no actinomycosis.

Summary.—The clinical course of this case was not that of blastomycosis or of any form of cancer. The large pits and cavities containing and forming white granules and abundant pus were unique. The edges were swollen, hyperplastic, livid —often showing soft-topped abscesses. (Compare with Case 2.). At times healing would occur in parts, with scars resembling those from an escharotic, or fire, but the scar tissue had no permanence, new abscesses occurring.

Case 2.—*Patient.*—Male, farmer, aged 36. About a year before the date of the examination mentioned below, he had picked a scaly papular lesion on the carmine border of the lower lip. He soon developed symptoms as at present. He then used a concentrated infusion of the leaves of the oxalis (sheep sorrel) and other caustics, destroying all but those rounded, retracted "hillocks" of the lower lip. The disease occurred below, with redness and swelling involving the whole chin and causing some enlargement of the submental glands. Each half of the chin had previously shown more marked involvement and later the lesion to the left of the left oral angle developed.

Examination.—May, 1905. There were four distinct areas, one in the sublabial fossa, one each side of the chin, one in the left oral angle. When the patient was examined first, the lower lip, down to the roots of the teeth, was destroyed save rounded remnants. On the base of the lip and on the upper chin were three semi-solid lesions; the cavities large and papillomatous, with small holes in the skin over them; the lesions full of pus and grayish-yellow granules. Just to the left of, almost in the left oral angle, lying between skin and mucous membrane was an unbroken lesion the size of a finger-tip. Incision exposed pus mixed with a quantity of granules somewhat like those from a sebaceous cyst, but firmer, slightly resembling small fish-roe. All the diseased parts were very sensitive. There was no impairment of general health.

Treatment and Clinical Course.—The lesion was cleansed with hydrogen peroxid and dressed with 1/1000 mercuric chlorid gauze, b. i. d. Granules and pus rapidly reappeared. A saturated solution of potassium iodid was given up to 47 drops t. i. d., and some iodism. No effect was produced on the disease. A sour odor was constantly present in this case, but not so intense as in Case 1. After a few days, the chin lesions having been well incised, the cleansing was followed, once a day, with application of 95 per cent. carbolic acid, not controlled by alcohol. This had only a little effect on the formation of granules and pus or the subcutaneous burrowing. The soft papillomata in the lesions were exceedingly vascular, bleeding freely on injury. They resembled somewhat the columnæ carnæ of the heart. A few seemed to have been blanched, forming at times whitish, coral-like clumps, but very vascular at attachment. *It is possible* that these were infiltrated with the disease bodies. There was a marked tendency of the chin infection to burrow, forming sinuses under the skin. *In these*, concealed, the white granules multiplied and pus formation continued in spite of cleansing and dressing twice a day. Nearly a month after the beginning of the treatment a new point appeared in the mucous membrane of the right lip remnant, as a small, discrete, whitish erosion from which a quantity of the seedlike grains were pressed, not mixed with pus. This formed a sinus a third of an inch deep. When the patient reached 66 m. saturated solution of potassium iodid t. i. d. with no benefit, the drug was stopped. He had fourteen *x*-ray treatments, getting primary reaction; a few beard hairs loosened. Dr. Hynds reported that he was unable to find or cultivate any growth, and saw nothing resembling blastomyces or actinomyces. When the patient was last seen after eight days' absence the verdict was reached that no treatment had been of any avail. The patient was reported to have died after rapidly increasing emaciation and gradual extension of the infection of the chin downward to the muscles of the throat and integument at the front, which left the bones bare. Death occurred about ten months after the date of first examination. Neither in this case nor in Case 1 was there any involvement of bone or periosteum.

This paper was begun nearly two years ago. The untimely death of Dr. R. W. Hynds, who did the microscopic work, together with my inability to obtain any notes of his observations, has embarrrassed me in attempting a proper report. I delayed finishing the paper in the hope, thus far futile, of getting another of those anomalous cases characterized by "granules and sour buttermilk odor." Clinically these cases bore not the slightest resemblance to the blastomycotic cases or to any of the published records of systemic, deep tissue and diffuse blastomycosis. I regret the absence of opportunity to have full histology and cultural work done on these cases, and my failure, at the time, sufficiently to appreciate them.

Characteristics were white granules, often the only contents of the cysts, deep subcutaneous abscesses, with inflammatory swelling around, hard and red, becoming darker and softer; and the strikingly peculiar odor. Should another case be found it would be of interest to investigate as to the probable presence and effect of the *Bacillus acidi lactici.*

Epithelioma, carcinoma, actinomycosis, tuberculosis, syphilis and typical blastomycosis were not suggested by any of the symptoms. If the cases were blastomycotic they were essentially as different from typical blastomycosis as granular, plus cutaneous, tuberculosis is from tuberculosis cutis verrucosa. This comparison offers the only basis for an effort to harmonize the cases I have reported with the descriptions of typical blastomycosis.

I am indebted to Dr. Oliver H. Ormsby, of Chicago, for references and suggestions.

1015 Century Building.

BIRTH OF QUADRUPLETS.

HENRY A. NAVE, M.D.

ARGENTINE, KANS.

Mother's History.—Mrs. L. C. T., aged 35, American, weight 112 pounds, height 4 ft. 6 in., married twelve years, had had seven children, of whom four are still living; two were born prematurely at six and seven months respectively, and one died at the age of three months, cause of death unknown.

Present Labor.—I was called to attend the patient July 19, at 1:30 a. m. The os and cervix were well dilated and the amniotic sac was protruding. Within ten minutes the first child, a boy, was born: it seemed small, and on tying the cord I was surprised to find four umbilical cords braided together. Within fifteen minutes another boy was born, thirty minutes later a girl, half hour later another boy.

Description of Placentas.—There were two placentas, one with three cords and the other with one. They were delivered in a macerated condition.

The Children.—The length and weight of the children were as follows: First child, length 9 inches, weight about 4½ lbs.; second, length 8¾ inches, weight about 3½ lbs.; third length 8½ inches, weight about 2½ lbs.; fourth, length 8 inches, weight about 2 lbs. In the case of the child delivered last it was necessary to resort to artificial respiration for a few minutes. The others breathed naturally. The children seemed normally developed, though small. The second child began to nurse on the second day and was apparently the only one able to swallow. The first-born child lived 24 hours; the second, 4 days; the third, 8 hours, and the fourth, 18 hours.

The mother's convalescence was uneventful except for a slight rise in temperature for a few days immediately succeeding delivery.

Therapeutics

METRIC SYSTEM VS. APOTHECARIES SYSTEM.

To the Editor:—In looking over the pages of The Journal devoted to therapeutics, I have frequently been surprised at the disparity existing between the apothecaries and the metric system when both were given.

In many cases the equivalents are not even approximately correct and are extremely annoying to those who employ the metric system exclusively as well as puzzling to those who occasionally use both.

In the issue of Oct. 14, 1908, pages 1336-37, twelve formulas are given in which eleven are not even approximately correct and are so strikingly contradictory in the equivalent values given that a plea for a closer approximation of values seems justified.

Despite its many so-called objectionable features, there are many physicians who employ the metric system exclusively in prescribing; therefore, this loose and careless manner of giving approximate values is pernicious in its effect by encouraging slovenly methods in prescribing, and not only tends to confuse the physician but subjects the patient to extra hazard from errors in prescribing.

If we are to have equivalents given, let us have them at least approximately correct. F. A. Carmichael.

The editor of the Department of Therapeutics is glad that Dr. Carmichael has brought up this subject for discussion. In the first place, the doctor does not quite understand the method with which the prescriptions which he criticises are written. If there were a stone wall between the prescriptions written in the metric system and the prescriptions written in the old system they could not be farther dissociated than they are intended now to be by the word "or." If the amounts were intended to be equivalent the sign of equality would be used. The hypothetic stone wall is represented by the word "or." This saves writing the ingredients of the prescriptions twice. It would, of course, be difficult for a devotee of the old system to attempt to convert his thoughts and doses from that system, in any given prescription, into the metric system directly opposite.

The prescriptions in both systems are written, i. e., the liquid ones, with the idea that the dose should be represented by a teaspoonful. It is foolish to consider that a fluidram is a teaspoonful, or that the metric system equivalent to a fluidram, 4 c.c., is a teaspoonful, because they are not. It should be recognized that a teaspoonful represents 5 c.c., considerably more than a fluidram, and that by the use of the teaspoon as a measure of dosage no three fluid-ounce mixture will ever represent twenty-four doses (as it does twenty-four fluidrams), but approximately eighteen doses, of 5 c.c. each, viz.: the three ounces would represent about 90 c.c. of fluid.

The criticism is naturally then made that we should insist on the use of medicine glasses graduated to fluidrams or graduated to cubic centimeters. While this is *theoretically correct*, few patients will obtain such graduated medicine glasses and take their medicine from them; hence the physician who always prescribes doses graded to 4 c.c. or to a fluidram will find that to the majority of his patients he is really administering a teaspoonful, or 5 c.c., or a fourth more than a fluidram. In other words, the majority of his patients would receive a larger dose than he intended.

The prescriptions written in the Department of Therapeutics are not aimed to instruct any physician how to transpose one system into the other. They are intended to be entirely dissociated, so that the men who write in the metric system should use the metric prescriptions if they approve of them, and the men who write in the old system should use the old system prescriptions if they approve of them. For instance, in the metric system, if the tincture of digitalis is ordered, 25 c.c. would be a correct and sensible amount based on the metric system; 30 c.c. or a fluid ounce is really absurd. If, on the other hand, it is for a devotee of the old system, then one fluid ounce is ordered. Naturally these two prescriptions differ by 5 c.c. or 1¼ fluidrams (or really more, as 31 c.c. is perhaps nearer the exact equivalent of 1 fluid ounce). However, when the dose is put down as ten drops, in water, three times a day, after meals, it does not make a particle of difference whether those drops are dropped from a bottle containing 25 c.c. or 30 c.c.

The criticism will then be made that a drop or a series of drops is exceedingly inaccurate dosage, that the dose should be measured in minim glasses or in glasses graduated to fractions of a cubic centimeter. This, too, is theoretically correct, but, except in institutions, practically useless. Not many of our patients will obtain such graduated glasses. Also the variation of where they will read, the demarkation between too much and too little in graduated glasses, in other words, as to where the meniscus of the fluid is, is such that variations will constantly occur of from one to three drops. Also when we recognize the variations in the strength of the different preparations, especially of tincture of digitalis, the dose can never be graded with measuring-glass accuracy. The dose is always enough for the object to be attained. In other words, if ten drops dropped by this patient or nurse from this particular bottle of this particular strength of tincture of digitalis is not sufficient, more must be given; if too much, less should be given.

Also the subject of exact scientific dosage becomes ridiculously absurd and hopelessly hopeless when we scientifically figure out the exact dose of a drug that we wish a patient to receive and the number of doses to order, and then find that more than frequently, unless the drug is a poison or the preparation is exceedingly strong, the pharmacist will not even bother to measure that preparation if it is a liquid, but will pour into his one, two, three or four-ounce bottle what he thinks is right, and our scientific mental processes are all useless.

Take, for instance, a simple desire on the part of the physician to put a fluidram of syrup of ipecac into a three-ounce cough mixture, or 5 c.c. of syrup of ipecac into a 100 c.c. cough mixture, just for the action of the small dose of ipecac on the bronchial mucous membrane, and he is astonished to find that time after time this supposed little bit of a dose of ipecac is nauseating his patient. It is easy to conceive what has happened when one works a short time behind a drug-store prescription counter. Also the variations in strength of the same preparation of the same drug bought at different drug stores makes the accurate measure of the final dose from the bottle absolutely useless. The dose of a drug or of a given preparation is always *enough, and enough can only be determined by the action of the first few doses.*

To go back to Dr. Carmichael's question of equivalents: Nothing has defeated the adoption of the metric system so much as has the endeavor to compute equivalents. The irregular metric figures of the physician who *thinks* in the old system and *writes* in the metric system is almost pitiful. If he wishes to write a prescription in the metric system, say for the sulphate of quinin, he should forget that a grain is 0.065 gram, but know that a small dose of quinin is 0.05 gram, and he may multiply this to what he wishes to give, whether 0.10, 0·15 or 0.20 gram. In other words, a dose of a drug that has a range of from 1 to 10 grains can not disturb a patient much by the variation of 0.1 or 0.015 gram. If one wishes to acquire the ability to write prescriptions in the metric system he should think of the metric system as dollars, cents and mills, and even forget dimes. If a dose of any drug is 10 grains, the range of dose is almost surely from much less to much more; consequently such a dose in the metric system would be 0.50 gram or 0.75 gram. If the dose of a liquid preparation is 1 or 2 fluidrams it certainly is also 5 cubic centimeters. If a dose is 1/60 of a grain it is, of course, simply 0.001 gram.

To reiterate, it is desired that all readers of the Department of Therapeutics should remember that there is no attempt at exact equivalents between prescriptions in the metric system and the same prescriptions in the old system, but each prescription in each system is intended to be absolutely correct pharmacally, chemically and therapeutically.

JOINT TUBERCULOSIS.

It can not be too frequently urged that a persistent disturbance in a joint should be suspected of a tuberculous cause. *If the trouble is tuberculous the sooner* the part is immobilized and the patient relieved of the depressing influence of pain and then given the best food and the most fresh, clean air treatment possible, the quicker his opsonic index rises and his ability to stay the disease is developed. In other words, the prognosis is good if the joint is properly treated early. If the diagnosis of the trouble in the joint is doubtful, the ocular tuberculin reaction may be tried, or possibly the von Pirquet cutaneous tuberculin reaction may prove as valuable in joint tuberculosis as it seems to be in early pulmonary tuberculosis. Chronic pain is so depressant to the nervous system, to the general nutrition, and to the circulation, as to prevent the normal healing power of the system. Consequently pain in a tuberculous joint must be stopped.

Dr. Edward H. Ochsner, Chicago (*Journal of the Michigan State Medical Society*, August, 1908), emphasizes the necessity of not only immobilizing a tuberculous joint, but of placing the muscles surrounding the joint "in accurate equilibrium," and contraction of the opposing muscles will not be caused and the pain will be diminished or prevented. With such care, morphin or other sedatives will not be needed (and no drug will prevent pain that will not also inhibit general nutrition).

Pain having been thus inhibited, the next aim should be to prevent secondary infection, and Ochsner states that fully 98 per cent. of patients with tuberculosis of the spine can be permanently cured if secondary infection is prevented. A cold abscess or a tuberculous breakdown Ochsner does not think should be classed as pus in the ordinary sense, and consequently should not always be evacuated; but if evacuated, every possible precaution should be taken to avoid secondary infection. A local tuberculous abscess is ordinarily a self-limited disease, but when complicated with secondary infection it becomes a serious malady. If secondary infection occurs, severer operations of removing sinuses, etc., must not be needlessly undertaken, as the patient gets well or improves from the ability of his blood serum to fight the toxins of the tubercle bacillus. An aid to his fighting power is furnished by injections of tuberculin after the method of Wright, but the proper dose and the proper time for such injections are determined by the patient's opsonic index. If the injection is administered at the wrong time his opsonic index will be lowered instead of raised. After any great depressing influence on the patient, as after a period "of poor food, poor ventilation, severe chilling, or the shock from an operation, or even when the patient is suffering from as simple a thing as obstinate constipation, it is not the time to inject tuberculin." This should be postponed until a time when the patient is beginning to rally from such depressing influences.

When there is secondary infection the prognosis, Ochsner says, has been much improved by not performing too serious operations, by using tuberculin injections, as indicated by a careful study of the opsonic index, and by treating the tuberculous sinuses by Dr. Emil Beck's method. Dr. Beck advises injecting into the tuberculous sinuses, "every two to four days, a sterile bismuth paste consisting of thirty parts of bismuth and sixty parts of vaselin at a temperature of 110 F." If after repeating this injection three or four times at the above intervals the sinus has not stopped discharging, it should then be injected "with a paste consisting of thirty parts of bismuth, sixty parts of vaselin, five parts of white wax, five parts of soft paraffin and one part" of the official liquor formaldehyd. Ochsner says that by these methods patients are not only more frequently cured, but the joints more frequently remain mobile. In other words, ankylosis is less likely to occur. He feels certain that prolonged immobilization of the joint does not tend to ankylosis, in fact quite the reverse, hence it should not be feared to keep a joint permanently immobilized too long.

In immobilizing a joint two things should be kept in mind: First, the joint must be at ease, with each surrounding muscle at rest and not stretched or irritated. Second, the splint should be as light as possible and still give complete immobilization. To accomplish the first object Ochsner fixes the diseased ankle joint with "the foot at a little less than a right angle to the leg." If it is properly applied the twitching of the muscles and pain will soon cease, and while it may be necessary for the patient to remain in bed for a few days, he may soon be allowed to go about on crutches. As soon as he can step on his foot without pain the crutches may be discarded, a soft leather shoe placed over the cast. and the patient allowed to resume his ordinary occupation.

The correct position "for the knee joint is immobilization at an angle of about 175°. The cast should extend from the tuberischium to the malleoli," but the whole cast should not weigh more than two pounds. So long as the knee is painful the patient may go about on crutches with a high-soled shoe on the other foot, but as soon as the patient can bear his weight on the affected leg without pain the crutches and high sole may be discarded.

"In the hip the position of muscle equilibrium is 10° of abduction and 5° of ventral flexion, and the cast should extend from the level of the umbilicus to a little above the knee." As a rule Ochsner would not apply extension, although sometimes it is advisable to use Buck's extension at night. The patient walking about with a crutch and a high sole under the other foot gives the necessary extension. Again as soon as the patient can bear his weight without pain Ochsner would take away the crutches and the high sole.

"In tuberculosis of the fingers, hand or wrist the cast should extend from the tip of the fingers to within two inches of the elbow, and the fingers, hand and wrist should be perfectly straight.

"At the elbow the cast should extend from the wrist to the axilla and the arm and forearm should be at right angles.

"In the shoulder the arm should be strapped to the chest with adhesive straps with a small triangular pad in the axilla. The cap is now applied over the shoulder and held in place with a soft roller bandage. The forearm is then placed in a sling."

Ochsner believes that the best cast is made of plaster-of-Paris applied over stockinette and then reinforced by wheat gluten bandages. The length of time a cast should remain in position can not, of course, be definitely stated, but as Ochsner believes that ankylosis is not caused by prolonged immobilization the cast should be kept on long enough, and in the case of the hip joint he makes it a rule to leave the cast in place six months after he is convinced the tuberculosis is healed.

If a patient be first presented for treatment with a very painful joint, partial ankylosis in bad position, and is emaciated, Ochsner would anesthetize the patient, place the joint in the position above described as the best, immobilize it, give subsequent hypodermatics of morphin sufficient to control pain and muscle spasm, and when such has entirely subsided, begin on the tuberculin treatment when the opsonic index shows it is indicated, this procedure, of course, being carried out in combination with the usual fresh-air treatment of the disease.

Acute Yellow Atrophy of the Liver in Pregnancy.—A. Bertino's monograph on this subject fills the *Ginecologia* of July 31, 1908. He has had occasion to observe nine cases of epidemic jaundice in pregnant women, including two in which it assumed a malignant form. He warns that jaundice in a pregnant woman, although apparently very mild, may at any moment assume the maligant form and develop into acute atrophy of the liver. The causes of this transformation into the graver form are manifold, but of most importance are those which induce changes in the parenchyma of the liver, which during pregnancy is in a condition of reduced resisting power on account of the extra work imposed on it and the possibilities for autointoxication. Twin pregnancy and affections of the blood (anemia), on account of the fatty degeneration of viscera. liable in this condition, may aid in transforming simple jaundice into the fatal form. The symptoms suggest an acute process of autointoxication, like eclampsia.

SATURDAY, NOVEMBER 28, 1908.

REPORT OF THE SURGEON-GENERAL OF THE ARMY FOR 1908.

In his annual report[1] for 1908 Surgeon-General O'Reilly gives some interesting information in regard to the health and sanitary conditions of the army at home and abroad. Admission, death, discharge and non-effective rates are all better than for last year and show progressive improvement since 1898. The improvement is principally in the group of preventable diseases, except tuberculosis and malaria. The admission rates for typhoid fever and for malarial fevers are the lowest of which there is any record in the surgeon-general's office.

As regards tuberculosis, the conditions are unsatisfactory. The measures suggested to control tuberculosis are greater care in the examination of recruits to exclude incipient cases, and better housing conditions, including larger initial air space and more effective ventilation. With regard to venereal diseases, it is hoped to accomplish something by teaching the enlisted men personal hygiene and by getting a better class of men, but it is not believed that any great diminution of non-effectiveness from this cause will be obtained until venereal diseases are included among the group of infectious diseases for which compulsory notification is required.

The most important causes of deaths from disease in the army for the year are, in the order of their relative importance, tuberculosis, pneumonia, cerebrospinal fever, typhoid fever and heart disease. Comparing the different countries in which United States troops were serving, it is shown that Alaska, as usual, had the lowest constantly non-effective rates, while the Philippine Islands had the highest. Comparing our own army with those of foreign countries, it is noted that our admission, death and non-effective rates are higher than in most other armies. This is not necessarily to be taken as indicating less effective sanitary precautions. There are many factors which must be considered in making this comparison. For instance, our army is the only one which includes in its admission rate cases treated in quarters, and while our death rate is higher than that of most other armies, yet when we are able to obtain a total loss rate, which is the sum of deaths and discharges for disability, our rate compares favorably with European armies. It is evident that by promptly discharging soldiers who are likely to die and allowing them to die out of service, a fictitiously low death rate can be obtained.

In regard to sanitation, the surgeon-general makes an appeal for more executive authority for his department in sanitary matters, and also that all special apparatus used in sanitary work and in the care and transportation of the sick, such as ambulances, water carts, water sterilizers, disinfecting apparatus, etc., should be purchased and supplied by the medical department. This seems such a reasonable and common-sense proposition that the wonder is it has not been done long ago. He speaks of the active anti-mosquito campaign which has been conducted for several years past and shows that the tremendous reduction in admission rate for malarial fevers is sufficient of itself to justify the additional cost of such measures. Attention is called also to the importance of house flies as carriers of disease, and, with a view to preventing the breeding of flies on military reservations, recommendation is made that all accumulations of stable manure should be kept in fly-proof rooms.

In Cuba a serious outbreak of typhoid fever which occurred in the preceding year is reported as being under control, although the admission and death rates are still much higher than in the United States. It is interesting to note that the medical returns show far less dysentery among the troops in Cuba than among those serving in the Philippine Islands. Indeed, it is believed that most of the cases reported from Cuba were recurrences of infections contracted in the Philippine Islands.

In the Philippine Islands all the rates were better than for the preceding year. The death rate, 6.92 per 1,000, is the lowest ever attained there. The principal factors in the improved morbidity and mortality statistics in those islands are the marked falls in the rates for malaria, dengue, and the eruptive fevers, diarrheal diseases and diseases of the skin. As concerns sanitation in the Philippine Islands, the surgeon-general recommends that at all permanent posts the construction of barracks and quarters should be of a permanent character. The buildings should be specially designed for tropical service; thoroughly screened against flies and mosquitoes; provided with porches to keep the sun's rays from the walls and with a concrete base to protect them from the subjacent soil dampness. Their construction should probably be concrete, with native hardwood floors and tile roof.

The Board for the Study of Tropical Diseases in the Philippine Islands reports the discovery of four cases of pulmonary paragonimiasis in one company of Filipino scouts serving in Samar, and two more in another company serving at the same station. They also report a fatal case of infection with the *Schistosomum japonicum* in a Filipino scout.

---

[1] Commented on in General News, The Journal A. M. A., Nov. 21, 1908.

The surgeon-general reports the reorganization of the Medical Department and the organization of the new Medical Reserve Corps in accordance with the act of April 23, 1908. Aside from the active members of the Reserve Corps, an inactive list has been constituted, which includes many of the most eminent physicians and surgeons in the United States. These men have consented to accept commissions in the corps without compensation and entirely from patriotic motives.

ENLIGHTEN THE PUBLIC ON FRAUDULENT MEDICAL CONCERNS.

In another column will be found details concerning a quack "institute" which has been excluded from mail privileges as a fraudulent concern. This makes the third article of the kind published in THE JOURNAL, the preceding ones being the Reinhardt case[1] and the Hibbard case.[2] These matters, of course, have little of scientific interest, and there are some, doubtless, who wonder why so much space is devoted to subjects that are really more fit for the general newspaper than for a medical journal. The answer is simple: The newspapers, as a rule, are so closely in bondage through their advertising columns to these concerns that, even if the matter were offered them, they would not publish it.

The present exposure is a typical exemplification of the tricks by which the public is constantly being defrauded. The assertions of the promoters of this fraud are typical of the falsehoods which underlie, so far as we have investigated, all these "cures;" for example, (1) that a new treatment, unknown to the medical profession, has been discovered, the actual fact being that the method is well known to, and used by, that profession for what it is worth, but with an understanding of its limitations; (2) that physicians of more than ordinary skill are employed by the concern, when, in fact, in so far as the work is done by physicians at all, such men are of low grade as to their grounding in general professional knowledge, and on good grounds, other than the present indictment, they are usually professional outcasts; (3) that individual care is given to the peculiar features of each patient's case; when, in point of fact, a stock diagnosis is made and a hotchpotch treatment applied, indiscriminately or with trifling or haphazard variations, to all alike—the very thing, the least appearance of which in a physician's dealing with his patient, leads to the resentful, but generally unjust, complaint, "He didn't pay sufficient attention to my case;" (4) that the treatment is harmless and not costly, while in fact the former claim is frequently untrue and the latter always so. It is simply an immoral mode of trading, in which the sale of a few cents' worth of material for tens, hundreds, or even thousands of dollars is forced by false pretenses on the individual, according to his available financial resources and his gullibility.

The facts presented are not new to physicians, who know that all these "mail order" concerns are, without exception, the schemes of swindlers—of vampires who prey on the ignorant sick or on those who have been led to believe they are sick *by the advertisements circulated by the concerns themselves*. The sufferers from consumption, locomotor ataxia, cancer, epilepsy and other more or less incurable diseases are a particularly easy prey. Like the proverbial drowning man, they are ready to grasp at any therapeutic "straw," however absurd or impossible it may seem to a rational mind. Even persons ordinarily sensible are, under these circumstances, so mentally unbalanced by reason of their condition that they are apt to credit as probably true the unscrupulous promises of cure held out to them by these ghouls.

Physicians may warn their patients of the fraudulent nature of these concerns, but unless they can enforce their "wise saws" with "modern instances," giving chapter and verse, their warnings almost certainly will be attributed to wrong motives and remain without effect. It is, therefore, to supply physicians with concrete and indisputable facts regarding these concerns that THE JOURNAL is publishing these articles and other similar ones to follow. But having done our duty in placing the facts at their disposition, it devolves on physicians to insure their wide dissemination. To publish these facts for physicians alone would be a work of supererogation; it is the public, and especially that portion of the public likely to be taken in the toils of these fraudulent impostors, which must have the information if it is to have any lasting effect. Valuable as was the exposure by *Collier's Weekly* of the "patent-medicine" fraud, its effect would have been only transitory had it not been for the wide and still continuing distribution of the revelations in pamphlet form from this office. This it is which has made Mr. Adams' article a living and powerful force to-day. In like manner it is our purpose to republish in pamphlet form, and at a nominal price, for distribution by physicians among their patients, the exposures of these quack medical institutes. We repeat, however, it rests with the individual members of the medical profession to use effectively the weapons which are provided them in the warfare against unscrupulous quackery and fraud.

LABORATORY GLANDERS.

The sad death of Dr. Thomas M. Wilson,[1] of Chicago, from acute glanders, in all probability contracted while engaged in experimental work with glanders bacilli, again illustrates the peculiarly grave dangers that surround workers with this bacillus. Probably no other germ has caused so many fatal laboratory infections, and the list of bacteriologists who are known to have lost their lives from accidental infection while studying the glanders bacillus is a long one, and no doubt it would be considerably longer still were it possible to collate all the cases of this kind. And then, too, there are also instances of final recovery after prolonged illness acquired in the course of laboratory work.

---

[1] THE JOURNAL, Oct. 3, 1908, p. 1144.

[2] THE JOURNAL, Oct. 17, 1908, p. 1330.

[1] Recorded under "Deaths" in this issue, p. 1888.

In some of the cases it is tolerably well known just how the occasion for infection arose, as, for example, through the breaking of a tube containing a culture of the bacillus and the spreading of the contents about the workroom or by some similar accident, but in many cases the infection has occurred without any known explanation of this kind and without any known failure in the usual precautions, so that it has seemed as if the bacillus were able to resist the usual methods of sterilization employed in routine bacteriologic work and thus to escape into the free environment of the worker. Indeed a well-known London bacteriologist is credited with the statement that he believes the glanders bacillus can withstand the sterilization the platinum wire ordinarily is given in the actual flame. Be that as it may, the bacillus is not regarded as especially resistant to heat and chemicals, and it is currently stated that it is destroyed by a temperature of 55 degrees C. in ten minutes and by 61 degrees C. in one minute, and, furthermore, that it is readily killed by a 5 per cent. solution of carbolic acid and a 1 to 5,000 solution of corrosive sublimate. The bacillus, however, is resistant to desiccation, the reported longevity under drying ranging from a few days to several months, and pure cultures are said to be more resistant than the bacilli in nasal exudate. Another feature of interest about many of these so highly regrettable laboratory infections is that the manner of entrance into the body by the bacilli is not at all clear, there being no primarily local symptoms to mark the point of invasion. It is believed that in such cases the bacilli pass directly through some part of the respiratory mucous membrane, perhaps most often the nasal, and thus cause the general infection. We know that small animals are easily infected by placing virulent material in the nose. That the bacillus has marked penetrative powers, resembling in this respect the pest bacillus, is shown by the experiments of Cornil and Babes, who produced glanders infection in guinea-pigs by placing a salve containing bacilli on the skin.

The great danger of the worker with glanders bacilli falling a ready victim to the gruesome and fatal disease they may cause makes it imperative that special precautions be taken to a much larger extent than probably is the case at this moment in the laboratories throughout the country. Investigative work with glanders bacilli is not to be lightly undertaken without due and competent consideration from all points of view. Veterinary, state and c[illegible] laboratories should be prepared to care in the most ideal way for all the infectious material sent them, because this may contain glanders material at any time. Finally, it should be impressed on the individual worker, especially the young and enthusiastic who stand at the beginning of a promising career and to whom the occasional case of glanders often seems to offer interesting problems, that the tradition about laboratory glanders is not a myth but a terrible reality against which he can not guard himself too closely.

THE NATIONAL CONSERVATION OF HEALTH.

In another department[1] appears the address delivered by *Dr. Charles A. L. Reed of Cincinnati*, at a public meeting held under the auspices of the New York Academy of Medicine, in which the problem of the conservation of the health of the nation is discussed in a broad manner, intelligible and convincing to the layman. Putting aside both the professional and humanitarian sides of the question, Dr. Reed considers the problem from a purely economical standpoint, appealing to the people to end the terrific and unnecessary waste of human life and energy occasioned by preventable illness and death.

That the question is timely is shown by the newspaper discussion aroused by Dr. Reed's address, for seldom has a professional utterance caused such widespread comment. By showing that the financial interests involved in the solution of this problem far exceed in magnitude those of the Army and the Navy combined, and that the advice and counsel of trained physicians and sanitarians are indispensable for its proper solution, Dr. Reed has proved, with mathematical accuracy, the right of the physician to claim a seat in the highest legislative body of the nation.

Particularly timely, in this connection, is an editorial in a recent number of the *Cleveland Medical Journal* entitled "Why Should a Physician Go to the United States Senate?" The editor shows, from an analysis of the membership of the Senate and House, that out of 162 occupations recognized by the United States census, only 19 are represented in the Sixtieth Congress, lawyers constituting 76 of the 91 members of the Senate and 273 of the 394 members of the House or 349 of the total membership of 486. In the Senate alone only 10 of the 162 occupations are represented. As the editor forcefully says, in the past questions of a legal form and technical detail have been the important considerations before Congress, while to-day sociologic and administrative problems are most imperative. The necessity of broader representation, as well as the value to legislative bodies of members possessing technical knowledge of sanitary matters, is evident.

The medical profession is asking for adequate representation in Congress not only as a privilege and right but as a duty which it owes to the public. The favorable comment aroused by Dr. Reed's address shows that when this issue is put fairly and plainly before the people, this duty will not only be recognized but insisted on and that the people will demand that the medical profession send some of its recognized leaders to Congress in order that they may point out the way to better sanitary conditions for the saving of human life and national resources.

---

[1] Special Article, page 1856.

Few, if any, members of the profession are better qualified to lead in such a work than Dr. Reed. His high standing in scientific circles, his experience on the Panama Canal Commission, his fearlessness and integrity combined with his well-known ability as an orator and debater, combine to fit him admirably for a seat in the United States Senate. In that body his ability as a leader would soon be demonstrated. Ohio, which has already furnished so many leaders and which proudly claims the next President of the United States as her favorite son, can render an additional and valued service to the nation by sending Dr. Reed to the Senate to lead in a great campaign for national health.

THE FOUNDATION OF ETHICS.

The reinstatement of ethics as an essential constituent of all practicable social and business relations moves onward. Business organizations are beginning to realize that without a general adhesion to sound principles of right conduct commercial anarchy must ensue. The basic idea of this proposition was clearly grasped and enunciated at a recent dinner of the Chicago Business Science Club. "It is well," said one speaker, "to strike at the serpents of greed and graft wherever they show their heads, but that is not enough; we must kill not only the serpents but their eggs, we must destroy their seed. . . . In a few years all of us will have been replaced by the generations now in the public schools. We must get back to the public schools to inculcate the science of right conduct in business." Here lies the root of the matter. It is in education—that is, not mere instruction in the facts of history, geography, science, mathematics, languages or what not, but in character building—that the justification is to be found of the saw, "The child is father of the man."

The proper preparation of the young man to fit him in all respects for the pursuit of his future career is of prime importance in the case of medicine. The relations of the medical man to the public are so peculiar, so much more intimate than the relations of other classes of men to the public, that a sound ethical training should take the first place in the equipment of the medical student. Religious education of any kind always includes the principles of ethics. The secularization of the schools which accompanied the establishment of the public school system, while doubtless as right as inevitable on general principles, carried with it the disadvantage of the exclusion of systematized ethical training, and no general steps have been taken to remedy this deficiency by the institution of definite ethical courses.

In like manner the abrogation of the practice of preceptorship from medical education has eliminated a practical training in that important part of the profession of medicine, the social relations of the practitioner with the public and with his individual patients. It is essential that partially to remedy the defect in medical training arising out of the discontinuance of the system of apprenticeship under a preceptor, the formal study of ethics as applied to medicine should have an important place in the medical curriculum.[1] While the place of the preceptor can not be filled by the medical college, every effort should be made, not only to inculcate ethical ideals, but also to impress on the medical student the fact that success in medicine does not depend alone on exact diagnosis and successful treatment, and that in practice he will have to treat patients, not "cases."

THE PUBLIC SERVICE OF PROFESSIONS.

The keynote of an admirable paper by M. L. Cooke[2] is found in Professor Hadley's address on the "Professional Ideals of the Twentieth Century," in which it is stated that "a man ought to have a clear conception of the public service on which his profession is based . . . a clear conception of the public service which his profession can render and the public duties which its members owe." It is as true of medicine as it is of engineering that (*mutatis mutandis*) there are "three parties interested, viz.: the engineer, his employer and the public." It is also as true of physicians (at least until very recent times) as of engineers "that the chief service rendered to the public by the . . . profession has been one rendered indirectly by serving well the second party interested—the employer." Mr. Cooke refers to the work already accomplished by the American Medical Association toward the establishment of a proper conception of the public services due from the medical profession to the public, as pointing the way for his own profession to follow. He cites the fate of the report of John R. Freeman on the Iroquois Theater disaster as an instance of the impotence of the most important investigations into the application of technical matters to the public good, in the absence of a supporting public opinion, which must be the result of education. "There is good reason to believe," he says, "that engineers have as much to gain from cooperation with the public as they have undoubtedly gained from cooperation with each other." This is equally true of the medical profession. Among the measures that he suggests for his profession are lectures to the public and the provision of at least one lecture on a technical topic of general interest at the national professional conventions; the formation of a committee to insure that information of the proper kind, having the requisite "news" character, shall be prepared for the use of the press: and other matters of a more limited scope. It is evident that a realization of public service as a duty of professions is in the air, and this should stimulate the profession of medicine to renewed efforts for the benefit of collective humanity.

---

[2] Journal of American Society of Mechanical Engineers, New York City.

Medical News

ALABAMA.

Medical Department Opens.—The regular session of the Medical Department of the University of Alabama, Mobile, opened October 5. Dr. William H. Saunders, state health officer, gave the opening lecture.——The opening exercises of the fifteenth session of the Birmingham Medical College were held September 30. Dr. G. W. Macon of Howard College and Dr. J. H. Phillips, superintendent of the Birmingham public schools, and others, made addresses.

Personal.—Dr. H. L. Hough, Florence, has been elected city physician by the Lauderdale County Medical Society.——At the meeting of Mobile County Medical Society, October 29, Dr. Douglas G. Campbell was elected county physician.——Dr. O. F. Cawthorn, Mobile, a trustee of Mobile Medical College, has presented to the institution portraits of four prominent physicians of the city, Drs. Anderson, Heustis, Ross and Gaines.——Dr. George R. Rau, Tuscaloosa, Birmingham, has been appointed demonstrator of anatomy in the medical department of the University of Alabama, Mobile.

Hospital Notes.—Papers of incorporation of the Sellers Hospital, Anniston, have been filed. The institution will be known as Union Hospital, and will be accessible to all physicians of the city. Drs. Edward M. and William D. Sellers are of the incorporators. The capital stock of the hospital is placed at $25,000.——Free medical aid for the sick and injured in Montgomery is announced by Dr. Gaston J. Greil, city health officer. A dispensary has been established, at which relief will be given during certain hours of the morning and afternoon, to all those who are unable to pay for medicine and treatment.

CALIFORNIA.

Medical College Under New Auspices.—Cooper Medical College, San Francisco, began its career as an integral part of Leland Stanford, Jr., University, November 3. It will henceforth be known as the school of medicine of the university.

Biennial Vital Statistics.—In the biennial report of the State Board of Health, it is shown that the births registered in the state for 1907 numbered 24,647, an increase of 3,673 as compared with 1906. The births included 12,645 boys and 12,020 girls. There were 23,005 marriages registered in the state in 1907, or 1,688 more than for the previous year. The deaths in the state numbered 31,095 for 1907, against 29,303 in 1906, an increase of 1,792, or 6.1 per cent.

The Afflicted.—Dr. Arthur Dangerfield, North San Juan, has gone to San Francisco, where he may be operated on for appendicitis.——Dr. Elmer E. Stone, superintendent of the State Hospital for the Insane, Napa, was operated on October 27, for appendicitis, and is doing well.——Dr. William W. Rumsey, Napa, underwent amputation of the third finger of the right hand, October 20, on account of infection.——Dr. William W. Fitzgerald, Stockton, who was operated on for strangulated hernia recently at St. Joseph's Home, is well on the road to recovery.

Personal.—Dr. Henry L. Nichols, for many years city physician of Sacramento, has resigned, and Dr. William K. Lindsay, acting city physician for the past year, has been selected to fill the vacancy.——Dr. William R. Dorr, warden of the City and County Hospital, San Francisco, has resigned.——Dr. Eugene C. Dunn has been selected as a member of the board of health of Fresno, vice Dr. Jackson L. Martin, resigned.——Dr. and Mrs. Edward W. Twitchell, Sacramento, have returned from Europe.——Authorization for the payment of a fee of $5,000 to Dr. Henry Harris, San Francisco, from the estate of Levi Shilling, was filed with the county clerk October 7.——Dr. William W. Cross, Jr., formerly of Visalia, has been appointed city bacteriologist of Fresno.

Society Meetings.—At the eighteenth annual meeting of the California Northern District Medical Society, held in Chico, November 10, the following officers were elected: President, Dr. Edward W. Twitchell, Sacramento; vice-presidents, Drs. William J. Hanna, Sacramento; Dan H. Moulton, Chico; and Albert Osborne, Hamilton City; secretary, Dr. Joseph W. James, Sacramento (re-elected); and censors, Drs. Wallace A. Briggs, Sacramento; Andrew M. Henderson, Sacramento; Samuel W. Langdon, Jr., Stockton; Walter E. Bates, Davisville; and John Fife, Red Bluff.——At the annual meeting of the San Mateo County Medical Society, held in San Mateo, November 9, Dr. Henry C. McClenehan, Belmont, was elected president; Dr. D. Brandley Plymire, South San Francisco, vice president; and Dr. Franklin M. Seibert, San Mateo, secretary-treasurer (re-elected).

Hospital Notes.—St. Anne's Maternity Hospital, Los Angeles, was dedicated with solemn ceremony, November 6.——As the result of "Tag Day" in San Francisco, more than $27,500 has been added to the building fund of the new Children's Hospital.——San Antonio Hospital, Upland, built only a little more than a year ago, is to have an addition of twelve rooms, which will practically double its capacity.——The Lower California Sanitarium Company has announced that it will erect a sanitarium on the border of Mexico to cost $125,000. Dr. Charles A. McQueston, Alameda, formerly president of the board of health of San Francisco, and Dr. Eduardo Liceaga, minister of health of Mexico, are said to be interested in the project.——Abbott Hospital, Richmond, has been incorporated with a capital stock of $25,000.——The San Francis Hospital Association, San Francisco, has purchased a site at Hyde and Bush streets, on which it will erect a hospital with accommodation for 200 patients.——The directors of the Peninsula Hospital, Palo Alto, have purchased a site, 225 by 275 feet, on Franklin Avenue, at a cost of $10,000. The main building will be 40 by 120 feet and is to be three stories in height and have a roof garden. The structure will be frame, covered with cement.——The Hospital and Health Committee of San Francisco have denied the application of the Oriental Hospital for leave to establish and maintain a hospital on Trenton street, between Washington and Jackson.

GEORGIA.

Tuberculosis Exhibit for Atlanta.—Steps have been taken by the Atlanta Antituberculosis Association to secure for exhibition in that city, the traveling exhibit of the National Association for the Prevention of Tuberculosis.

District Society Meeting.—At the annual meeting of the Sixth District Medical Association, held in Macon November 11, Dr. Alfred F. White, Flovilla, was elected president; Dr. James W. Cowart, Walden, vice-president, and Dr. Eugene B. Elder, Macon, secretary-treasurer (re-elected). The next meeting will be held at Indian Springs.

ILLINOIS.

Diphtheria Antitoxin Purchased.—The state board of health has placed a contract for diphtheria antitoxin for free distribution. The antitoxin will be sent to 200 agents in the state, who will issue it as required to physicians. The legislature appropriated $30,000 for this work.

Contagious Diseases in Chicago.—During the week ended November 21, there were 788 cases of contagious disease reported, distributed as follows: Diphtheria, 214 cases; scarlet fever, 212; tuberculosis, 127; chickenpox, 68; measles, 58; typhoid fever, 42; pneumonia, 25; whooping cough, 17, and minor diseases, 24. Compared with the report of the preceding week, this shows 22 cases fewer of diphtheria and 21 fewer of typhoid, an increase of 10 cases in scarlet fever and double the number of chickenpox cases.

Deaths of the Week.—The mortality report of Chicago for the week ended November 21 shows 596 deaths, equivalent to an annual death rate of 14.34 per 1,000, an increase of 31 over the preceding week and of 61 over the corresponding week of 1907. Consumption was the leading cause of death, with 77. Other principal death causes were: Pneumonia, 63; acute intestinal diseases, 54; nephritis and heart diseases, each, 50, and violence (including suicide), 38. There were reported 23 deaths from diphtheria, 13 from scarlet fever, 6 from measles, and 5 from typhoid fever.

Personal.—Dr. E. C. Dudley and family, Chicago, have returned from Europe. During his stay in Vienna, Dr. Dudley was elected an honorary member of the American Medical Association of Vienna, being the third individual to be thus distinguished, the preceding honorary members being Dr. Politzer of Vienna and Dr. William W. Keen of Philadelphia.

——Dr. B. G. R. Williams, formerly of Danville, has moved to Paris and has established a laboratory for the use of the physicians in the surrounding territory. In addition to the ordinary microscopic and chemical analyses, the modification of milk will be undertaken in this laboratory.——Dr. Daniel R. Brower, Chicago, has been appointed a member of the state committee having in charge the investigation of the Cook County Insane Hospital, Dunning.

KANSAS.

Do Not Want Publicity.—The Wilson County Medical Society, at a recent meeting, adopted a resolution requesting all newspapers in the county to refrain from mentioning physicians' names in connection with medical or surgical cases.

Kansas Missionaries in China.—Dr. J. M. Wright, formerly of Topeka, has returned to that city on a visit after nearly five years' work as a medical missionary at Tak Hing, Chow, China.——Dr. J. P. Todd, Topeka, is in charge of a hospital in Canton.

Must Not Sell Cocain.—The Kansas City Board of Health has taken up actively the cause of those fighting the sale of cocain, and has issued the following notice to all druggists within its corporate limits: "I hereby notify all druggists or drug clerks or other individuals who sell, give away or dispose of cocain or other narcotics without a prescription from a reputable physician, that they will be prosecuted to the full extent of the law, favors shown to none.

(Signed) J. A. FULTON, Secretary Board of Health."

MASSACHUSETTS.

Certified Milk for Worcester.—The October meeting of the Worcester District Medical Society, at which the Homeopathic Medical Society and milk dealers of the city were guests, was devoted to milk problems. Dr. Lester C. Miller presented a paper on "Fat-Free Milk"; Dr. Roy J. Ward, one on "Results Obtained at the Clean Milk Station Conducted Last Summer by the Fresh Air Fund"; Dr. Francis H. Slack of the Boston Board of Health, one on "Bacteriologic Examination of Milk," and Dr. R. M. Merrick, chairman of the Norfolk District Medical Commission, one on "The Value of Inspected Milk in Infant Feeding." The society voted to establish a milk commission and appointed the following members: Drs. George E. Emery, Merrick Lincoln, Lester C. Miller, Roy J. Ward, Charles L. Nichols, Edwin R. Leib, Prof. Leonard P. Kinnicutt, and T. Hivers Gage, Jr., representing the staff of the Worcester Board of Health. The commission organized with Dr. Nichols, chairman, and Dr. Ward, secretary-treasurer, and hopes soon to have supplies of certified and inspected milk to recommend to the profession.

Personal.—Dr. George H. M. Rowe, for thirty years superintendent and resident physician of the Boston City Hospital, resigned November 4. He will be succeeded by Dr. John H. McCollom, who was formerly in charge of the contagious hospital.——Dr. B. Swayne Putts has resigned his position at the State Sanatorium for Tuberculosis, Rutland.——Dr. Walter Channing, Brookline, has been appointed chairman of the board of trustees of the Hospital for the Insane in the Metropolitan district of Boston. This is under the provision of the new law, whereby the insane of Boston are to be cared for by the state in the same way as those of other towns and cities of the commonwealth. The present institutions are to be continued, but under the direction of this new board, instead of the former city board.——Dr. Paul H. Provandie, Melrose Highlands, has been appointed associate medical examiner for Middlesex County, and Dr. William O. Faxon, Stoughton, medical examiner for Norfolk County.——Dr. Guy G. Fernald, Boston, for many years a member of the staff of the McLean Hospital, Waverly, has been appointed resident physician of the Massachusetts Reformatory.——Dr. B. R. Rickards, director of the bacteriologic laboratory of the health department, Boston, has resigned to take charge of the laboratory of the state board of health, Columbus, Ohio.——Dr. Frederick L. Brush, Boston, has been appointed superintendent of the New York Post-Graduate Medical School and Hospital.——Dr. Burdett L. Arms, Boston, has been appointed assistant director of the bacteriologic laboratory of Boston.——Dr. Edward H. Trowbridge has been appointed president of the Worcester board of health.

MICHIGAN.

Personal.—Dr. Carl J. Larson, a member of the staff of Negaunee Hospital, has resigned and will be succeeded by Dr. P. S. Wilson, Grand Rapids.——Dr. Edwin R. Campbell, Flint, has, it is announced, decided to give up practice and will go into the automobile business.

Undergraduate Medical Association.—A number of the members of the senior and junior classes of the medical department of the University of Michigan perfected an undergraduate medical association last spring under the name "Medical Review of the University of Michigan, the membership of which is made up principally of assistants and members of the senior and junior classes. Meetings are held monthly, at which papers are read and matters of interest to the medical department and profession are discussed. This is entirely a student's organization, and the primary object is to get undergraduates actively interested in the matters pertaining to his chosen profession. In addition to the miscellaneous papers, the organization has started a systematic study of the history of medicine.

MISSOURI.

College Now in Good Standing.—After an inspection made recently by a committee of the Missouri State Board of Health, Barnes Medical College, St. Louis, has been restored to good standing by that board.

Fund for Hospital.—Mercy Hospital, Kansas City, will receive a fund of $10,000. Mr. J. W. Semple of Cripple Creek, Colo., donated $1,000 on condition that the hospital raise $9,000 by November 15. Of this, the final $1,000 came from Mr. J. L. Loose of Kansas City.

Visiting Physicians Appointed.—The board of health of Kansas City has appointed the following as the officers of the staff of visiting physicians of the General Hospital: President, Dr. Jabez N. Jackson; vice-presidents, Drs. Jefferson D. Griffith and C. Lester Hall, and secretary, Dr. J. Park Neal.

Resolutions.—The St. Joseph-Buchanan County Medical Society, at its meeting November 11, adopted resolutions urging the establishment of a national health bureau, and the enforcement of local ordinances prohibiting spitting on sidewalks and in public conveyances and the inspection of meat in butcher shops, slaughter houses and packing houses.

NEW YORK.

Harvey Society Lecture.—The fourth Harvey Society lecture, delivered November 28 by Dr. Wilhelm Falta of the University of Vienna, is on "The Therapeutics of Diabetes."

Volunteers Wanted.—The committee on scientific work of the New York State Medical Society is now preparing the program for the coming meeting. Those who wish to read papers are requested to communicate with the chairman, Dr. Leo H. Neuman, 194 State Street, Albany.

Pleads Guilty.—James Doty, indicted at Rochester for illegal practice of medicine under a diploma issued in another's name, is said to have pleaded guilty of practicing medicine without a license, in the Genesee County Court, November 11. The maximum penalty for the offense is one year in the penitentiary and a fine not to exceed $500.

Alumni Election.—At the annual meeting and dinner of the King's County Hospital Alumni Association, held in Brooklyn November 16, Dr. James W. Ingalls was elected president; Dr. George E. Corterno, vice-president, and Dr. Franklin B. Van Wart, secretary-treasurer, and Dr. Victor A. Robertson was re-elected historian, all of Brooklyn.

Personal.—Dr. Joseph Fowler, police surgeon of Buffalo, is reported to be ill at his home.——Dr. Alfred Mercer, Syracuse, said to be the oldest practitioner in central New York, celebrated his eighty-eighth birthday anniversary November 14.——Dr. Hugh McGee, Buffalo, has been appointed national medical examiner of the Postoffice Clerks' Insurance Association.

Academy Incorporates.—The Buffalo Academy of Medicine filed papers of incorporation in the office of the clerk of Erie County November 10. The object of the society is to promote the science of medicine and maintain a medical library and museum. The directors, who also act as the council, are as follows: Drs. Edward A. Bowerman, Harry R. Trick, William Irving Thornton, Grover W. Wende, Thomas F. Dwyer, Charles S. Jewett, Julius Ullman, Thomas J. Walsh, Lawrence Hendee, Thew Wright, Earl P. Lothrop, Edward C. Mann, James A. Gibson, Frederick J. Parmenter and Allen A. Janes.

NORTH CAROLINA.

Communicable Disease Prevalence.—The State Board of Health reports for October that measles was prevalent in 5 counties, whooping cough in 16 counties, scarlet fever in 25 counties, diphtheria in 39 counties, typhoid fever in 59 counties, pneumonia in 18 counties, malarial fever in 17 counties, and smallpox in 3 counties.

Physicians in the Legislature.—Among the 121 members-elect of the legislature are the following physicians: Drs. John A. Pickett, Burlington, Alamance county; Mark B. Pitt, Old Sparta, Edgecombe county; James R. Gordon, Jamestown, Guilford county; Mahlon Bolton, Rich Square, Northampton county; and Robert P. Floyd, Riley, *Franklin county.*

Personal.—Dr. Mary E. Lapham, Highlands, left November 17, for Davos Platz, Switzerland, for the winter to study the methods *in vogue there in the treatment of tuberculosis.*——Dr. Walter B. Mott, Mount Mourne, had a cerebral hemorrhage November 13, and is seriously ill.——Dr. Earle Grady, Tryon, who has been seriously *ill for two months, is reported to be* convalescent.

State Tuberculosis Hospital Opened.—Dr. James E. Brooks, Greensboro, superintendent of the State Hospital for Tuberculosis, announces the opening of the institution, which was authorized by the legislature two years ago, and is located *in the Sand Hill section of Cumberland county, eight miles* from Aberdeen. Eight patients have thus far been admitted to the institution.

State Antituberculosis Society to Meet.—The annual meeting of the North Carolina *State Association for the* Prevention of Tuberculosis will be held in Charlotte, Jan. 12, 1909. The convention will be officially opened by the governor; Dr. J. Howell Way, Waynesville, will respond to the address of welcome, and addresses will be made by Drs. Edward L Trudeau, Saranac Lake, N. Y.; Herman M. Biggs, New York City, and others.

The Polk County Leper.—Secretary Cortelyou in an official statement issued November 7, relative to the case of John R. Early, formerly a soldier in the *Philippines, and a citizen* of Polk county, who contracted leprosy, which was discovered a few months ago when he was in Washington under orders from the pension department, decides under the recent opinions in the case filed by the attorney general against deportation of Earle to North Carolina or elsewhere from the District of Columbia, where he is at present under guard. Mr. Cortelyou holds that while he has authority to make regulations to prevent the introduction of contagious or infectious diseases into a state or territory or the District of Columbia from any state, he has no authority to make any rule by which Early can be deported from Washington, D. C., or whereby North Carolina can be required to receive him.

Directors Protest.—The directors of the State Hospital, Morganton, at a recent meeting, entered a formal protest against the recent action of the State Hospital Commission in declining to add to the existing plant of the State Hospital for the Insane, Morganton, until the State Hospital for the Insane at Raleigh had been enlarged and made to accommodate as many as the former institution; and furthermore, in ordering all tuberculosis cases in the Raleigh *institution to be conveyed to* the Morganton institution, which is situated in the mountains. The directors of the latter institution propose to stand on their rights under the law regarding the *control of the admit*tance to the institution under their care and state they will refuse to receive patients ordered from the eastern district by the Hospital Commission, or tubercular insane from outside the limits of *Morganton district as prescribed* by law.

OHIO.

Will Not Prescribe Liquor.—At a meeting of the Hancock Medical Association, November 17, a resolution was adopted *that no member* should give a prescription for liquor excepting at the bedside of patients, and then only in case of extreme urgency.

Personal.—Dr. S A Hitchcock, Lima, while alighting from a car November 6, fell and fractured his left hip——Drs B S Perry and Eugene A. Smith, district physicians of Cleveland, have resigned, and Dr. Frank Roth has been appointed Dr. Smith's successor——Dr. Starling Loving Columbus, on November 13, celebrated his eighty first *birthday anniversary*

Injunction Against Chiropractic Dissolved.—The Sixth Circuit Court, November 14, is said to have refused to grant the injunction of Dr Charles H. Merz Sandusky, acting for the Erie County Medical Society, to enjoin H. L Murchison, a so-called 'chiropractic," from practicing because he did not have a certificate from the State Board of Medical Examiners The ground on which the injunction was dissolved was that the property rights of Dr. Merz, who inaugurated the legal contest, had not been interfered with, as claimed in his petition

Requirements of Ohio Pure Food Law.—The Dairy and Food Commission of Ohio, Columbus, calls attention to the requirements of the Ohio law, which are that milk shall contain not less than 12 per cent. solids and 3 per cent. fats; that milk from which a *part of the fats* has been removed shall be labeled and sold as skimmed milk; that there is *no fixed* standard for cream; that condensed milk shall be made from whole milk; *that butter shall be made* wholly from pure milk products; that renovated or process butter shall be *made* wholly from pure milk products and shall be labeled and sold as such; that *oleomargarine is an imitation* of butter, not made wholly *from pure milk products* and shall be labeled and sold as such, and shall be free from artificial coloring matter; that cream, including *cream cheese,* Ohio state full cream cheese, or full cream cheese shall be made wholly from pure milk products and shall contain not less than 30 per cent. butter fat; that skimmed cheese shall be *made* wholly from pure milk or cream and may contain less than 30 per cent butter fats; that filled cheese is an imitation cheese, not made wholly from pure milk products, and shall be labeled and sold as such; that milk shall not be sold from cows fed on unhealthy feed, from cows fed on wet distillery or starch waste from diseased or sick cows, from cows kept in a place that is unclean or in an insanitary condition, from cows kept in a *cramped or unhealthy condition;* when water or other foreign substance has been added, or when it is unclean, impure, unhealthy or unwholesome.

PENNSYLVANIA.

Philadelphia.

Personal.—*Dr. Charles W. Dulles, for fifteen years lecturer* on medical history in the University of Pennsylvania, has resigned——Dr. Morris H. Tindall has resigned as medical inspector in the *Bureau of Health.*——*Dr. Benjamin F Stahl* has been elected medical director of St. Agnes Hospital——Dr. W. Howard Lyle has been appointed a medical inspector in the *department of health.*

Aid Association Officers Elected.—At the annual meeting of the Aid Association of the Philadelphia County Medical Society, November 9, the following officers were elected: President, Dr. James B. Walker; vice president, Dr. Jacob R. Shellenberger; secretary, Dr Lewis H. Adler, Jr.; treasurer, Dr. John B Turner, and *directors for three years, Drs. John B. Rob*erts, De Forrest Willard and William T. Hamilton

Cocain Seller Sentenced.—Morris Stein, recently arrested on *the charge of selling cocain* unlawfully, pleaded guilty in quarter sessions court, November 13, and is said to have been sentenced to two years' imprisonment Two other persons charged with similar offences were *sentenced to six months' imprison*ment The judge, in passing sentence, denounced Stein as worse than a common criminal, and a trafficker in souls.

Extending Medical Organization.—*The first step in a more* systematic enrollment into the county medical society of physicians as yet unaffiliated with any professional organiza*tion, was taken, on suggestion of the committee* for increase of membership, by the naming of the following auxiliary committee: Drs. James H. Baldwin, James B Walker and David Riesman. The so-called "Illinois" plan of a paid organizer is to be investigated.

Academy of Medicine Projected.—*Announcement is made of the filing in the county prothonotary's office of the proposed charter of the* "Philadelphia Academy of Medicine," a corporation, the object of which *is the education and* mutual improvement of its members in all matters pertaining to the art of medicine, and by means of lectures, demonstrations and the presentation of papers, *the encouragement of study in* all departments of medical science.

Public Meeting.—The Philadelphia County Medical Society *has decided that,* on December 15, it will repeat its successful public meeting of last year. The society recognizes the necessity of the systematic education of the public as to the true status of the medical profession on such subjects as protection of the masses against epidemic diseases, *animal* experimentation, model laws to guard against criminal and incompetent practitioners *and like great sociologic questions.* At a recent business meeting of the society $100 was allotted for this purpose, and the following executive committee was named: Drs Lewis H Adler, Jr., Alexander R Craig, Samuel P. Gerhard, Samuel W. Gadd and John J. Gilbride.

Health Report.—The total number of deaths *reported for the* week ended November 14 aggregated 483, an increase of 62 over the previous week and of 55 over the corresponding week of last year. The principal *causes of death* were: Typhoid fever, 10; measles, 2, scarlet fever, 8; diphtheria, 13; consumption, 65; cancer, 26; diabetes, 4; apoplexy, 11; heart diseases, 53; arteritis, 8; *acute* respiratory disease, 48; enteritis, 22; hepatic cirrhosis, 6; appendicitis, 5; Bright's disease, 51; premature birth, 8; congenital *debility,* 7; senility, 6; suicide, 2; accidents, 21, and marasmus, 4.——There were 215 cases of contagious disease reported, with 32 deaths, or 63 more cases and 9 fewer deaths than were reported in the preceding week.

Tuberculosis Exhibit.—At a meeting of physicians and laymen with Mayor Reyburn, November 9, it was decided to bring the exhibit which was displayed at the International Congress on Tuberculosis to Philadelphia. It was planned to raise $10,000 to secure the exhibit. The mayor was chosen honorary chairman, and the following permanent officers were elected: Chairman, Dr. Joseph F. Neff; secretary, Dr. Joseph Walsh, and treasurer, E. T. Stotesbury. An organization to be known as the Allied Associations for the Prevention of Tuberculosis, and composed of representatives of nearly every hospital and medical organization in the city, was formed, with Dr. Neff as chairman. The following committees were formed: Committee for procuring exhibit from New York, Dr. Lawrence F. Flick, chairman; finance, Mr. John Wanamaker, chairman; hall and arrangements, Dr. Charles J. Hatfield, chairman; publicity, Mr. James Elverson, chairman; committee on lectures, Dr. William W. Keen, chairman, and woman's auxiliary, Miss Mary Richmond, chairman.

New Home for Epileptics Opened.—The Eastern Pennsylvania State Institution for the Feeble Minded and Epileptics, Spring City, was formally opened November 16. Six buildings have been completed at a cost of $250,000. Temporarily the institution will admit only men, but, when the other buildings are completed, women and children will be cared for. Twenty-three buildings are to be erected at a total contemplated cost of more than $1,000,000, and the institution will occupy a site of over 300 acres. The six buildings already constructed comprise a dining hall, accommodating 600 persons, with a kitchen adjoining, a power plant furnishing heat and light and manufacturing ice for the entire institution, an industrial building, provided with work benches and machinery for the inmates, two dormitories capable of accommodating more than 250 patients, and a teachers' home, which will be used as the administration building for the present. Dr. Henry M. Weeks, president of the International Society for Epileptics, has been appointed superintendent, and the following men have been elected to the board of trustees: John P. Crozer, president, Upland; John B. Lober, treasurer, Philadelphia; Samuel A. Whitaker, secretary, Phoenixville; Drs. Wharton Sinkler, Philadelphia; Joseph K. Weaver, Norristown; T. C. Detwiler, Lancaster, and George B. R. Umstead, Phoenixville; Henry W. Comfort, Fallsington, and B. Whitman Dambly, Skippack.

FOREIGN.

Centennial of Medical Instruction in Brazil.—The National Academy of Medicine at Rio de Janeiro celebrated October 3 the hundredth anniversary of the founding of the medical departments in the universities of Rio de Janeiro and Bahia in Brazil. The session was open to the public, with the president of the academy, Prof. A. Nascimento, in the chair. Five gold medals were awarded, one to the president of the republic and one to the minister of the interior, who were both present, the others being given to the deans of the medical faculty at Rio and Bahia. A souvenir volume edited by F. Figueira was also a feature of the celebration. The *Brazil Medico* of October 8 gives the addresses in full.

PARIS LETTER.

(From Our Regular Correspondent.)

PARIS, Nov. 12, 1908.

Disturbances in the School of Medicine at Paris.

As noted in THE JOURNAL at the time (Nov. 30, 1907, xlix, 1853), in consequence of riotous protests by the Paris medical students against the appointment of Professors Nicolas and Prenant of Nancy to fill the chairs of anatomy and histology at Paris, the dean ordered the Paris medical school closed until Dec. 31, 1907. No further trouble was experienced during the remainder of that school year; but, since the end of the summer vacation the rioting of the students of the first and second years has prevented Professor Nicolas from giving his courses. The dean, realizing that by closing the school the previous year he had punished the innocent with the guilty, called on the police, who arrested the rioters and took them before the courts. The measure was, no doubt, rather harsh; but students and pretended students could not be permitted to burn the school furniture, as they did at Professor Nicolas' opening lesson.

Mission for the Study and Prevention of Yellow Fever.

Although the epidemic of yellow fever in Martinique has been actually on the wane since October 31, the Minister of the Colonies has despatched thither a mission for the study and prevention of the disease, under the direction of Dr. Simond, who, in 1902, took part in a similar mission to Rio de Janeiro for the especial purpose of submitting to critical tests the conclusions of the American military commission at Havana in regard to the rôle of the *Stegomyia fasciata* in the transmission of yellow fever. The present mission is to ascertain and apply immediate measures to prevent the spread of the epidemic now raging at Fort de France and sending out infection toward European ports, especially Nantes and St. Nazaire.

Ordinance in Regard to Preserved Foodstuffs.

The Superior Council of Public Hygiene having called attention to the dangers to consumers of preserved foods put up in boxes decorated with lead paints or varnishes, the president of the council of ministers has forbidden the manufacture or sale of boxes of food so painted or varnished. In order to give manufacturers and merchants the time to close out their stocks, the measure will take effect after Aug. 1, 1909. It applies both to imported and domestic commodities; foreign goods coming under the ordinance will be held at the customhouse.

Medicine and Politics.

Two recent incidents have shown the deplorable consequences of the encroachment of politics on the sphere of medicine. A physician in the customs service, having been elected councilor of arrondissement on a platform which was not acceptable to the administration on September 21 received his dismissal from the customs, to date from October 1, on the ground that his political attitude had been judged incompatible with the functions of a physician of the customs. Medical opinion is agreed that this abrupt discharge of a physician from a position which he has held for years constitutes a violation of liberty of opinion altogether unworthy of a republican government. The syndicate of physicians in the neighborhood of the dismissed physician has decided unanimously that none of its members will accept the position.

The other instance is much more serious, for it implicates a physician. During the judicial proceedings in regard to the *émeute* or uprising of Villeneuve-Saint Georges, one of the counsel for the accused found among the documents in the case a letter from a hospital surgeon (who is also physician to the ministry of the interior), giving information against one of his patients as having been concerned in the disturbances. This fact has naturally aroused much feeling. The counsel for the accused are going to address to the Minister of Justice a protest demanding the prosecution of this physician for violation of professional secrecy. Moreover, two physicians have just addressed to the president of the syndicate of physicians of the Seine a letter suggesting that the syndicate notice "this glaring violation of professional secrecy under particularly revolting circumstances" by some severe measure, such as a public reprimand.

BERLIN LETTER.

(From Our Regular Correspondent.)

BERLIN, Nov. 5, 1908.

Campaign Against Tuberculosis.

By a decree of the Prussian Ministry of Education (*Kultus minister*) it has been ordered that apartments which have been vacated by persons suffering from tuberculosis of the lungs or of the larynx shall be disinfected before occupation by a new tenant at the expense of the community or of the district or of some other association prepared to assume the expense (such as insurance companies for sickness, age or invalidism).

Feeding of Poor School Children.

By a resolution of the Berlin Council it is directed that in the coming winter 8.000 poor school children shall receive warm dinners in the soup kitchens. The same privilege is to be extended to children not of school age on the recommendation of charitable societies.

Crusade Against Lupus.

The German central committee for the fight against tuberculosis has lately instituted a systematic campaign against lupus. As a basis of the measures to be taken (foundation of sanatoria for phototherapy, etc.), the number of lupus patients in the various parts of Germany is first to be determined. For this purpose question blanks have been sent out to the German physicians, in which information regarding the number, sex and age of the patients, as well as regarding the disease, is asked for. These circulars will be collected by the government officials and statistical tables worked out from them.

Health and Recreation Resorts for Children

According to a report of the director of the public charities in Hamburg, there existed in Germany in 1906 the following institutions for children: 41 sanatoria in salt water bathing resorts, with 4,472 beds; 22 seashore sanatoria, with 2,164 beds; 28 sanatoria in health resorts, with 1,304 beds; 6 sanatoria for pulmonary patients, exclusively children, and 10 sanatoria for pulmonary patients in which children are also received, which together provide 283 beds. In addition there were the so-called vacation colonies, in which children needing recuperation are cared for during the summer vacation; nineteen forest recreation stations, etc. All together 66,299 children were cared for in 1906 in all these sanatoria and convalescent stations.

VIENNA LETTER.

(From Our Regular Correspondent.)

Vienna, Nov. 8, 1908.

Appointment of a New Professor of Anatomy.

The post of director of the anatomic museum and lecturer on human anatomy at the University of Vienna, made vacant by the resignation of Hofrat Toldt, who wishes to finish his life work, the "Anatomic Atlas," has been offered to Prof. S. Hochstetter, who has been assistant to Toldt, Langer and Zuckerkandl, and is well known by his researches on the phylogenetic development of the heart and blood vessels.

Increase in Height and Improvement of Physique in Austria.

The recently published reports for 1908 of the army recruiting officers contrast remarkably with those of former years in respect to the number rejected and the average health and physique of the recruits. Every male Austrian subject must present himself three times, between his twenty-first and twenty-fourth years, unless previously finally rejected, for compulsory military service. The requirements were not severe: a minimum height of 155 cm. (5 feet) and a minimum chest measurement of 83 cm. (33 inches). In former years 30 per cent. had to be rejected. Since 1903 a constant improvement in nearly all respects has been observed. The number of myopic, hypermetropic, underfed and crippled youths has diminished until this year not less than 90 per cent. could be pronounced fit. Of those rejected, 60 per cent. came from the rural districts and 40 per cent. from the towns; the grounds of rejection were bad hearing, bad physique and bodily malformation. It is interesting to note that in 1899 the physical requirements for recruits had to be lowered in respect to eyesight and hearing. It is now at least 4 diopters for myopic, 2 diopters for hypermetropic, with 6/12 visual acuity with correcting glasses; hearing in both ears for the whispered voice at not less than three feet, and for the conversational voice at not less than twelve feet. The average height of the Austrian recruit this year is 167 cm. (5 feet 5 inches), an increase of 3 cm. in ten years. The reasons for the improvement of the national physique are not clear, for the improvement in general health and standards of life has not been such as to account for it.

New Hospital with One Thousand Beds.

To celebrate the sixtieth anniversary of the emperor's reign, the municipality of Vienna has decided to found several charitable institutions. One is a hospital with over 1,000 beds; its corner-stone has been laid by the emperor. There will be a surgical ward with 150 beds, two wards for internal diseases with 150 beds each, 150 beds for the open-air treatment of phthisical patients, and the remaining 400 beds will be devoted to gynecologic, otologic, ophthalmic and laryngologic cases. There will also be attached to the hospital a pavilion with 150 beds for paying patients, making 1,150 beds in all. The institution will comprise 19 pavilions, including the necessary laboratories, a library and a pathologic institute. The cost is estimated at about $2,250,000, in addition to the value of the site, which is already owned by the city. At the same time, 5 pavilions, with 120 beds each, will be added to the existing children's hospital as "Emperor's Jubilee Pavilions," so that over 1,700 hospital beds will be added to the existing number in a year's time. It is to be hoped that this addition will be sufficient to do away with the abominable condition now justly complained of, the lack of space being such that dying patients could not be brought into the hospital.

Pharmacology

"Distinguished Turpitude."

"Our friends the medicine men seem to be perking up a bit of late. Orangeine is advertising that it cures headaches, cold, grippe, and indigestion by 'removing the cause.' It 'cures' these things on the same principle that by hitting a man on the brain with a club you may 'cure' his headache until his consciousness revives. Antikamnia also shows signs of making claims as false as those made before the exposures; and some, in spite of their evil, are positively diverting, thus:

"PRACTICAL PRESCRIPTIONS

"Alcoholism—(After Debauch) Antikamnia & Codein Tablets.
"Dose:—One every two hours. Teaspoonful Tr. Gentian Comp. three times daily in water."

"Among the other diseases thus prescribed for are ague, asthma, backache, biliousness, 'car sickness,' catarrh (defined as or recognized by 'pain in head'), 'change of climate,' 'chest pains,' colds ('to stop quickly') consumption ('chest pains'!) delirium tremens, delirium from fever, drunkenness, epilepsy, intermittent and remittent fever, hay fever, hiccough, hysteria, locomotor ataxia, 'threatened pneumonia,' sciatica, seasickness, 'shopper's headache,' St. Vitus' dance, toothache, whooping-cough, and 'worry'! Verily, the supply of suckers is forever inexhaustible, and the 'patent-medicine' bunco game will, doubtless, pick up as the public forgets the information which it recently acquired."

The above is from *Collier's Weekly*. Orangeine and Antikamnia—Antikamnia and Orangeine! Has it come to the pass that mere laymen shall class the great "ethical proprietary" Antikamnia with the plebeian "patent medicine" Orangeine? Banish the thought! And yet, who knows; possibly within the year we may see in the street-cars and elevated trains, sandwiched between posters describing Shac and Orangeine, advertisements extolling the virtues of Antikamnia. One pictures the homeward-bound suburbanite, clinging wearily to a strap in an overcrowded street-car, with the ferrule of a fellow-passenger's umbrella intermittently gouging his intercostal muscles and an obese female standing stolidly on one of his feet. What would be the psychic effect on such an individual of having to face an advertisement which read:

> FEELING IS A SENSE.
> FEELING PAIN
> NONSENSE.
> TRY TWO ANTIKAMNIA TABLETS.

In the language of the immortal Hashimura Togo, "We enquire to know."

Elegant Specialties.

Practically all manufacturing pharmaceutical houses put out more or less—usually more—"ethical proprietaries" for the use of doctors who do not have time to formulate and write individual prescriptions for individual patients. While most of these preparations would be more correctly classed as nostrums, they are always labeled "specialties" in the price lists of the manufacturers.

In the price list of Stearns and White Co., Chicago, the description of one of their "specialties" reads:

> "Sulphozone.—This product is a compound and somewhat complex assimilation of natural gases acted on by Sulphur Dioxid in an aqueous solution, producing other gases of oxygen in reaction."

Evidently this is intended as a succedaneum for the late liquozone.

The composition of another "specialty" is thus given:

> "Modernopolt.—The body proper of this most excellent product is a clay formation of the Silician age—to which is added in suitable quantities Boric Acid

and Methyl Salicylate thoroughly incorporated in pure Glycerin and augmented by the valuable action of Camphophenique."

In the elegant and classic language of the editor of the *California State Journal of Medicine*, "Ain't it rotten, Rosie?"

Pharmacists and Postgraduate Courses.

Physicians have already demonstrated the value of well-organized local postgraduate courses and are extending and elaborating such work. That similar courses adapted to the profession of pharmacy would prove of value has been recognized by the Philadelphia branch of the American Pharmaceutical Association. The members of this body recently attended the first of a series of free lectures and demonstrations in the Postgraduate Course of Instruction for Local Pharmacists. The topic was "The Application of the Microscope in Pharmaceutical Practice," which was presented in detail by Professor Henry Kraemer. These lectures offer a valuable and unique opportunity to those pharmacists who are interested in the professional side of their work, and the Philadelphia pharmacists are to be commended on the progressive step they have taken. It is to be hoped that this work may be extended all over the country, and become a permanent feature in local pharmaceutical societies. It is needed.

Correspondence

A Plea for Esperanto in International Medicine.

LEWIS, Kan., Nov. 16, 1908.

To the Editor: I wish to answer your Paris correspondent's question in THE JOURNAL, Oct. 10, 1908. Speaking of the advantages accruing from the use of only one language in international medical congresses, he says: "The ideal, however, would evidently be to adopt for communications and for discussions a single language, as has been done for international relations. Some believe that only a new, artificially created language, such as Esperanto, is capable of answering the requirements; but is it not chimerical to think of adopting an artificial language when it would be much simpler to use a living one?" Then he goes on to urge the use of French.

Certainly, one can not deny that one language only would be the ideal—not only for medical, but for all international relations—but with the correspondent's conclusion as to French and Esperanto, many will take issue, even many who are not partisans of the latter. It is strange that any one living in this age of invention, using daily the railway, telephone, automobile, and the thousand other artificial improvements, should object to an artificial language. In our utilitarian world the only questions that should be considered in selecting a tongue for international use are:

1. Does it answer all requirements of communication as well as or better than any other?

2. How does it compare with others in difficulty of acquirement?

3. What are the relative obstacles in the way of its adoption by all nations?

I submit that the only language that satisfactorily fulfils the above demands is Esperanto, because:

1. Four great international world congresses have fully shown that Esperanto is adequate to express ideas of every character. Technical terms already used internationally are changed only enough to make them conform to the Esperanto endings. Medical writers will find that Esperanto will convey as clearly as German all shades of meaning.

2. That Esperanto is more easily learned than any other modern language is due to the fact that the obstacles met with in most modern languages do not exist in the new tongue: (a) The spelling is absolutely phonetic and deals with elementary sounds easily acquired by any one, no matter what his native language. Experience has shown that people of all nationalities pronounce this language with the least residual native accent. (b) There are no exceptions to any grammatical rule and only 16 rules! (c) There are no irregularities of word formation, and the inflections for person, number, case, tense, etc., are reduced to a minimum. (d) There are few synonyms and no words with the same sound and different meanings, except as the unforeseen results of word building. (e) It is more widely international in its elements than any other tongue. (f) It has a system of word building which renders it one of the most flexible mediums in the world for exact and varied expression, and at the same time does away with five-sixths of the vocabulary ordinarily to be memorized by the student of a new language.

3. Having no race prejudices or national jealousies to combat, as any national tongue will always have, Esperanto has a great advantage in the race for international preferment.

I have learned more Esperanto in eleven months (since I first took it up from reading the note in THE JOURNAL, Nov. 30, 1907) in the odd moments of a busy practice than I have been able to learn of French and German since I began their study in college in 1893. In the brief period named I have learned to read Esperanto readily without dictionary, to write it easily and to speak it slowly. That is many times as well as I have done with either of the other languages. Frankly, I doubt if I ever could master the French pronunciation or the German gender and construction. And a lot of smarter people than I am are in the same fix.

ELMER E. HAYNES, M.D.

Instruction on Medical Ethics.

NEW YORK, Nov. 16, 1908.

To the Editor: I am repeating this season the course of instruction in the Principles of Medical Ethics, which was received with enthusiasm by the members of the graduating class last year. Only two or three sections of the booklet are considered at one time, and this after the completion of a lengthy conference on practical surgical topics. The same enthusiastic interest is displayed now by the students that characterized the last year's course. The students are anxious, indeed, for copies of the Principles of Medical Ethics, so that they may be able to follow the instructions with greater advantage to themselves, for obvious reasons. I, therefore, request that you will send me for use a copy for each member of the graduating class. It is much better to place them thus early in hand than to wait until after graduation. This course of action is so obvious as to need no further remark. As soon as suitable progress is made in this manner I will again request of the students individual queries bearing on medical ethics which may occur to them to make. No doubt the illuminating experience in this regard which developed further need for this deviation in the manner of instruction last term will be equally manifest again. I hope that all other institutions engaged in medical instruction will see the need of this ennobling activity and accordingly enter on it. It is far better, it seems to me, to start aright in this field of professional adornment, with early success, than later to labor harder with a comparatively disappointing outcome. In any event, I am anxious that the medical man graduating from the college which I have the honor to represent shall be afforded the opportunity to become as gracious and just in manner and method as he is equipped in professional attainments.

JOSEPH D. BRYANT.

[COMMENT: The above is published because it comes from one who has had experience in discussing, before senior medical students, the philosophy of ethics as it relates to medicine and because it gives us opportunity to call the matter to the attention of those in other medical colleges who are interested in the subject. As heretofore, the American Medical Association stands ready to supply, without charge, to the authorities of every medical school, a sufficient number of copies of the Principles of Medical Ethics so that one may be placed in the hands of each senior student. We have usually sent out these copies in February, but we think an earlier distribution, as suggested by Dr. Bryant, is an improvement. Authorities of medical schools may therefore apply at once for the number desired. It is hoped, however, that something more will be done than merely to distribute booklets. No medical college should allow its graduates to enter on their life work unless they have received at least one lecture on ethics as it relates to medicine and to medical conduct. In this connection we call attention to an editorial in this issue.—Ed.]

A Literary Description of the Psychic Phases of Tuberculosis.

Chicago Heights, Ill., Nov. 10, 1908.

To the Editor:—The remarkable paragraph by Charles Dickens which I enclose occurs in "Nicholas Nickleby," forty-ninth chapter, third paragraph. It seems to be noteworthy, not only on account of the beautiful use of language, but also as a description which leaves little doubt as to the nature of the disease.

"There is a dread disease which so prepares its victim, as it were, for death: which so refines it of its grosser aspect, and throws around familiar looks unearthly indications of the coming change—a dread disease, in which the struggle between soul and body is so gradual, quiet, and solemn, and the result so sure, that day by day, and grain by grain, the mortal part wastes and withers away, so that the spirit grows light and sanguine with its lightening load, and, feeling immortality at hand, deems it but a new term of mortal life—a disease in which death and life are so strangely blended, that death takes the glow and hue of life, and life the gaunt and grisly form of death—a disease which medicine never cured, wealth warded off, or poverty could boast exemption from—which sometimes moves in giant strides, and sometimes at a tardy sluggish pace, but, slow or quick, is ever sure and certain."

E. M. Barnes.

Medical Economics

A GENERAL PLAN FOR A SCHEDULE OF MEDICAL FEES.

By J. N. McCormack, M.D.

BOWLING GREEN, KY.

I have long held the opinion that it was feasible to frame a plan for a schedule of medical fees which could easily be modified, as to the amount of the charges and other details, to meet the conditions and needs of almost any county or locality in any section of the country. As the plan I have in mind would be for the information, guidance and benefit of the public quite as much as of the profession, it involves conferences and a full understanding with the people of the community beforehand, as well as the fullest possible publicity afterward, through the public press, placards in each office, and otherwise, the explanatory footnote being made an essential part of every publication.

One of the main difficulties about this in the past has been the almost universal, but wholly erroneous, opinion and insistence on the part of both profession and laity that all the physicians of a community have an equal value and should make the same charge for their services. We know full well, and in a way and to an extent that the people can not, that nothing could be further from the truth. Because of the faulty system of medical education, loose medical laws, and lack of local organization and incentives to study, in vogue in this country until recent years, there are regularly licensed physicians in almost every community in the United States, in cities and towns quite as abundantly as in the country districts, who are well paid for all they know or can do for their patrons when they receive anything, and I insist that the time has come for us to deal frankly and openly with each other and the public about this and all other matters of common interest. It is essential to the success of such a plan, too, that we abandon once and forever the antiquated notion of penalties for those who do not live up to the schedule or blacklists for those who do not pay for services. Such harsh methods are contrary to the spirit and purposes of real organization and, in the very nature of things, can only be productive of misunderstandings and odium.

I have made rate-cutting and cheap doctors a matter of special study in every section of the country for years, and have come to have much sympathy for this class. On getting down to bottom facts, I have always found that they charged less for their services because they honestly knew, better than any one else did or could, that they were worth less than their competitors, and that this was their only chance to obtain or hold practice. There may be exceptions to this, but I have never found one that would bear investigation. They have my sympathy for another reason. As with the division of fees and commissions, contract and lodge practice, the use of proprietaries and nostrums, and similar mistaken practices and policies, all more hurtful to the people than to the profession, the fault is far more with the schools which pretended to educate these men than with them. In fact, without proper instruction about these matters during student life, so as to make it a part of their very being, just as important to the future physician and his patrons as instruction in anatomy or physiology, and sometimes with bad examples from their teachers to start them in the wrong direction, the wonder is that more of them do not do worse. These are just the men who most need the uplifting influences of county societies and postgraduate courses, they are actual entities with which we must live, associate or contend, and with tact and judgment many of them can be made competent. To suspend or expel them is far more of a punishment to their innocent patrons than to them, and it destroys the only chance of reclaiming them.

What is first and most needed in dealing with this class, for their own good as well as of the people, is to raise their earning capacity, to make them better practitioners and better men, by means of consistent, persistent postgraduate study, and by the influence and example of the higher grade members, in every county society and in such intercourse as comes in daily practice, and then in leading them to the adoption of systematic business methods and aiding them in other ways in securing better compensation. If we could substitute common sense plans of cooperation, the idea of a real community of interests, of practical, kindly helpfulness, such as is common between lawyers, in the place of the habit of fault-finding, jealousy and aloofness which is still as easy to find as it is disgraceful between the physicians of many communities, the difficulties of this entire problem would be reduced to a minimum.

The county societies and postgraduate courses furnish the facilities for doing the scientific and social features of this work. For the business side of it I am advising that the profession in each county or city consider the advisabality of arranging for systematic monthly collections, with a carefully selected business representative, and a centrally located "medical collector's office," the collector to be under bond, and on a definite salary, and with authority to appoint as many assistants as may be necessary, for whom he is responsible, very much as sheriffs and city collectors do The collector should be a man of tact and judgment, he should hold the affairs of each physician as strictly private and confidential, and he should be well paid. This plan should not be tried anywhere until good scientific work is well under way and a spirit of harmony secured, until all of the details have been worked out with the kind of business representatives indicated, and until public sentiment is prepared for it. Even in large cities the plan is worthy of consideration for colony and office buildings, wards or other convenient groups, if it can not be made available for the entire profession. It will not be easy to do these things in any community, in fact, it is never easy to do any important reform work which is worth doing, but with such preparatory work as has been suggested, and with tact and judgment in the earlier steps, I am convinced that the plan could be made as pleasant and convenient for the people as it would be helpful and profitable to the profession.

In most parts of the northwest and on the Pacific Coast the rate of charges sanctioned by custom is sufficient to sustain a competent and equipped profession, but in many sections of the eastern, middle and southern states, outside the large centers of population, and for a large part of the profession in them, all except the surgical fees are wholly inadequate, and this is operating to the disadvantage of both the profession and people now in a way unknown to our forbears. This country in recent years has passed through an era of most remarkable prosperity, but physicians and other professional classes have not shared in it With the cost of living almost doubled, and the cost of equipment for modern practice quadrupled, the income of medical men, except surgeons and specialists, has remained about stationary. Properly interpreted, poverty in the profession. and the lack of equipment and practical incompetency inseparable from it, is just as important to the public as to us, and the subject should be boldly discussed in public meetings and in the periodical and daily press until this real, positive danger to the people is a matter of common knowledge. Not only the higher standard of competency, but the increased usefulness of the profession in other ways should be made plain. It now probably does more real charity than all the other vocations combined, but the generous support to which it is entitled, and which is demanded by the highest humanitarian interests, would enable it to do a systematic, intelligent, discriminating relief work which is now impossible. To an extent not dreamed of by the laity, or even by many in the higher ranks of the profession, a large per cent. of the physicians in this country, in cities and towns as well as in the rural districts, on account of poverty and the pressing needs of their own families, are daily forced to take what is almost blood-money from a class of widows, teachers and working-women, in their times of affliction, whose incomes are so scanty when well, that it would and should be an honor and a pleasure to make them the special wards and beneficiaries of a properly supported profession.

The opportunity has come to me to study this whole question as no other man probably has ever been able to do I am giving the results of this broad experience in my public talks every evening, and find, in the lay discussion which follows, that the people can be made to appreciate our difficulties and their dangers quite as readily as can the profession. In truth, unpleasant as is the admission, the trouble is with us and not with the public, as is true in regard to almost every other evil from which we suffer. If the physicians competing for the same practice in every section of the United States could really get together in all these matters, and then take the people into their confidence, the balance would be comparatively easy, as there are not enough of them to do the practice if every patient was given the time, and the kind of scientific examination and treatment, to which they are entitled

For many reasons, any schedule intended for general adoption should cover only the ordinary fees for general practitioners and non operative office work. Surgical fees are usually the subject of special arrangement, and, anyway, they vary to such an extent that an attempt to include them would give the public an exaggerated and misleading notion of what is received by the ordinary surgeon, or by any of them except under extraordinary circumstances, and would do more harm than good As a rule, too, surgeons and specialists are better paid and are well able to take care of themselves. Besides, my experience has convinced me that it is in the field of general and office practice, with the hard worked and underpaid ordinary practitioners, that the pressing need for reform exists.

For obvious reasons the schedule should be adopted by the profession as a whole, or as individuals, and not by the county society. The provision in the by-laws forbidding such action by the societies was inserted after careful consideration, was certainly wise under the conditions then and still existing, and probably should be permanently retained. The membership in most societies embraces only about from one half to three-fourths of the physicians of the county. While it is probable that all, including the former sectarians, will finally come in, this will be the work of years, and although not absolutely essential, it is important that the schedule be agreed to practically by all of the active physicians of the jurisdiction, whether members or not Besides, this has been one of the most fruitful sources of discord in societies in the past, often provoked by those who took least interest in the scientific proceedings.

With all the foregoing considerations in mind, and after the matter has been fully discussed with the people. the schedule and footnote, in their main features, are suggested only as the basis for discussion. The rate of charges will seem too high for some sections and entirely too low for others. I am proposing about what, in my judgment, would be fair and equitable at the present cost of living and equipment in the central, middle, western and southern states, but, of course, the exact fees and other details must be arranged for each community in accordance with what is deemed just and proper. The rates should not be too hard and fixed. There are people of moderate circumstances in almost every community, factory operatives and others, who ought to pay something, and yet should not pay full fees, and a wise discretion on this and similar points must be provided for in any plan which is to be comprehensive and successful.

The order of arrangement and the items of practice included are as seems best suited for most counties and communities, but the purpose is to make it so simple and flexible that it can be altered to suit varying conditions and views. For instance, if it is thought best, fees for fractures and dislocations, or any other surgical or special work, can be easily added. It will be noted that a broad distinction is made between ordinary and complete office examinations, including a thorough examination of the chest, urinalysis and other like work involving extra time and skill. My own opinion is that a double charge should be made for night practice for well-to-do people, but I have yielded to the views of others on this point. Telephone practice is so annoying, exacting and unsatisfactory that it certainly should be paid for except where regular visits are being made, and in all cases after bed time. Consultations are purposely made low in order to develop and encourage this variety of practice

The form of schedule suggested and the footnote, as they should go on the placard, are as follows:

SCHEDULE OF MEDICAL FEES FOR ——— COUNTY.

1. Day visit in town	$2 00
2. Night visit in town	3.00
3. Day visit in country, first mile, $2 00; each after mile, one way	1.00
4 Night visit in country, first mile, $3 00; each after mile, one way	1.50
5. Ordinary office examination and advice	1.00
6 Complete examination and advice	5 00
7. Advice or prescription by telephone	1 00
8 Obstetric case, uncomplicated, not over 6 hours	15 00
9. Life insurance examinations	5.00
10. Consultation, double ordinary visit.	
11. Surgical and other special fees as may be arranged.	

EXPLANATORY NOTE.

This schedule of fees is purely advisory. It is arranged and published for the information and guidance equally of the profession and people It is intended to suggest the fees for ordinary services by competent physicians, for these fully able to pay their bills It in no way applies to practice for the deserving poor, of which all agree to do their full part It may be that physicians who are less competent will feel that they should charge less for their services This is recognized as just, and to do so will in no way affect either their society membership or professional standing It is especially important that these less fortunate members should have the benefit of the postgraduate study courses and other scientific work of the county society, which are free to all, for their own good as well as that of their patrons and regular attendance at these meetings should be made a condition of continued employment Night fees are made higher for many reasons, but more especially to give time for such study and society work as is essential in *keeping a physician* competent to practice with safety to the people

For the convenience and benefit of both the profession and its patrons systematic monthly collections, in so far as possible, are requested in the future It is believed that it will be more satisfactory to families to settle their accounts while they are small, and while they remember and are grateful for the services, and it will enable physicians to keep equipped for far better service

---

POSTGRADUATE COURSE FOR COUNTY SOCIETIES.

DR JOHN H BLACKBURN, DIRECTOR.
Bowling Green, Kentucky.

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course]

Fourth Month: Third Weekly Meeting.

DISLOCATIONS.

Classification.—Compound. complicated, multiple, complete and incomplete. traumatic. pathologic, congenital, ancient or unreduced, recurrent. spontaneous.

Etiology.—Predisposing causes, anatomic peculiarities, age, sex, occupation; exciting causes, indirect or direct violence, muscular action.

Pathology.—Injury to ligaments and capsule, injury to bone and cartilage, to blood vessels, to nerves.

Treatment.—Anesthetic, reduction; obstacles to reduction, portions of capsule, muscle, tendon, bone.

Special Dislocations.

Lower Jaw.—Varieties, treatment.

Clavicle.—1. Sternal end: (a) forward, (b) upward, (c) backward. 2. Acromial end: (a) *supra-acromial*, (b) subacromial, (c) subcoracoid. Diagnosis and prognosis in each variety.

Shoulder.—Frequency, age, sex, character of injury. Pathologic anatomy. 1. Anterior or forward; (a) subcoracoid, (b) subclavicular. 2. Downward; subglenoid, with subvariety, *the erect*. 3. Posterior or backward: (a) subacromial, (b) subspinous. 4. Upward; supraglenoid. Diagnosis; (a) subcoracoid, *inspection*, palpation, abduction; Dugas' test. (b) Subclavicular. (c) Subglenoid, inspection, palpation, abduction, measurements. (d) Subspinous and subacromial. Diagnosis of complications. (a) Fracture of humerus. (b) Injury of vessels and nerves.

Elbow.—1. Of both bones of forearm: (a) Backward (backward and outward or backward *and* inward). Pathology, lateral ligaments, flexors and brachialis anticus, coronoid process; *fractures and* injuries to vessels and nerves. Diagnosis and treatment. (b) Lateral (incomplete inward and outward, or complete outward). (c) Forward (with or without fracture of olecranon). (d) Divergent (anteroposterior and transverse). 2. Of ulna alone (backward and upward). 3. Of radius alone (forward, backward and outward). 4. Unreduced dislocations of elbow. Due to interposed capsule. 5. Unreduced dislocations of elbow. Due to interposed capsule, muscle or bone. Treatment, arthrotomy.

Wrist.—1. Lower Radio-ulnar Joint. 2. Radio-carpal Joint. (a) Dorsal, backward dislocation. (b) Forward dislocation. 3. Carpal Bones. (a) Mediocarpal *joint*. *(b)* Isolated displacement. 4. Carpometacarpal Joints.

Phalanges.—1. Metacarpo-phalangeal Joints. (a) Thumb. Pathology and treatment. (b) Fingers. 2. Interphalangeal Joints of Fingers.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week *ending* Nov. 21, 1908:

Geddings, E. G., and Quinton, W. W., capts., ordered to report at Washington, D. C., for examination for promotion.

Cox, Walter, and Bispham, W. N., capts., ordered *to report* at Manila, P. I., for examination for promotion.

Persons, E. E., *capt.*, relieved *from duty* in *Philippines* Division; will sail Dec. 15, 1908, from Manila for San Francisco.

Worthington, J. A., first lieut., relieved from duty at General Hospital, Presidio of San Francisco, and assigned to duty as surgeon of transport *Crook*.

Pinkston, Omar W., first lieut., relieved from duty as surgeon of transport *Crook*.

Bloombergh, H. D., capt., *relieved from duty* at Fort Leavenworth, Kans., and ordered to San Francisco, to sail Jan. 5, 1909, for Manila, for Philippine service.

Purnell, H. I., capt., relieved *from* duty at Fort Mackenzie, Wyo., and ordered to San Francisco, for duty as surgeon of *the transport Thomas* on its next voyage; on arrival at Manila, to report for duty *in* Philippines Division.

Reasoner, M. A., first lieut., relieved from duty as surgeon of transport *Thomas*.

Jones, H. W., first lieut., relieved from duty as surgeon of transport *Buford* about *Jan.* 15, 1909, and *ordered* to the United States.

Harvey, P. F., col., left Chicago on leave of absence.

Ragan, C. A., capt., left Ft. Monroe, Va., on leave of absence for 10 days.

Appel, D. M., lieut.-col., granted leave of absence for 30 days.

Lemmon, R., M.R.C., granted an extension of 15 days to his *leave of absence*.

Guittard, A. M., M.R.C., ordered to active duty, and *directed* to proceed to Fort Logan, Colo., for duty.

Escobar, Julius A., M.R.C., fell into open well at Imus, Cavite, P. I., Nov. 15, 1908, *and* was drowned.

Slayter, John T. H., M.R.C., *honorably* discharged from the service of the U. S.

Dougherty, James C., M.R.C., ordered to active duty *at* the expiration of his present *leave of* absence.

Murray, Wilson, M.R.C., *ordered to* active *duty at the* expiration of his present *leave of* absence, and *directed* to proceed to Fort William Henry Harrison, Mont., for duty.

Tignor, Edwin P., dental surgeon, ordered to Forts Howard and McHenry, Md., successively, for temporary duty.

Montgomery, W. O., and Mansfield, T. O., contract surgeon, contracts annulled, their services being no longer required.

Navy Changes.

Changes in the *medical corps, U. S. Navy*, for the week ending Nov. 21, 1908:

Dessez, P. T., P. A. surgeon, orders to the Pacific fleet modified; ordered to temporary duty *at the* Naval Hospital, Mare Island, Cal.

Anderson, F., *medical inspector*, detached from the Navy Yard, Mare Island, Cal., *and ordered to* command the Naval Hospital, Annapolis, Md.

Lowndes, C. H. T., surgeon, ordered *to the* Navy Yard, Mare Island, Cal., and to additional duty, in command of the Naval Medical Supply Depot at that place.

Vickery, E. A., P. A. surgeon, *detached* from the Naval Hospital, Annapolis, Md., and ordered to the Naval Hospital, Boston.

Fauntleroy, A. M., P. A. *surgeon, detached* from duty at the Naval Medical School Hospital, Washington, D. C., and ordered to duty at the Naval Hospital, Annapolis, Md.

Hayes, G. M., P. A. surgeon, unexpired portion of sick leave revoked; ordered to the Naval Recruiting Station, *Baltimore*.

Brooks, F. H., asst.-surgeon, detached *from* the Naval Hospital, Boston, Mass., and ordered to the Naval Recruiting Station, Cleveland, Ohio.

Munson, F. M., P. A. surgeon, detached from the First Torpedo Flotilla on board the *Decatur, and ordered to treatment* at the Naval Hospital, Canacao, P. I.

Kelly, H. L., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the *Decatur* for duty with the *First Torpedo Flotilla*.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and other *officers* of the Public Health and Marine-Hospital Service for the seven *days ended Nov. 18, 1908*:

Kerr, J. W., asst.-surgeon-general, detailed *to represent* the service at the *Convention* of Mayors of North Carolina at Charlotte, N. C., Nov. 17-18, *1908*.

White, J. H., surgeon, granted 8 days' leave of absence *en route* to join station.

Cumming, H. S., P. A. surgeon, granted 1 *month's* leave *of* absence from *Oct. 29, 1908*.

Billings, W. C., P. A. surgeon, detailed as a member of a revenue cutter service retiring board at Baltimore, Md., *Nov.* 18, 1908.

Francis, Edward, P. A. surgeon, granted 10 days' leave of absence from *Dec. 1, 1908*.

Burkhalter, J. T., P. A. surgeon, detailed as a member *of a revenue cutter* service *retiring* board at Baltimore, Md., Nov. 18, 1908.

Porter, Joseph Y., sanitary *inspector, title changed* to read "quarantine inspector," from Dec. 1, 1908.

Barnes, W., acting asst.-surgeon, granted 21 *days' leave of absence from Dec.* 10, 1908.

Blanchard, J. F., *acting* asst.-surgeon, granted *2 days'* leave *of* absence from Nov. 11, 1908.

Browne, R. W., acting asst.-surgeon, granted 29 days' leave *of* absence from Nov. 20, 1908.

Carter, P. I., acting *asst.*-surgeon, granted 5 *days' leave* of absence *from Nov.* 2, *1908*.

Curley, *C. P.*, acting asst.-surgeon, granted *3 days' leave of* absence from *Nov.* 18, 1908, under Paragraph *210. Service Regulations*.

Dynan, N. J., acting asst.-surgeon, *granted 1 day's extension of* leave *of absence on account* of sickness, Nov. 4, 1908.

Lyall, Robert, acting asst.-surgeon, *granted 4 days' leave of* absence from Nov. 6, 1908, without pay.

Marcoe, W. W., acting asst.-surgeon, granted 30 days' leave of absence from Dec. 2, 1908.

Stearns, H. H., acting asst.-surgeon, granted 28 days' leave of absence from Dec. 4, 1908.

Thompson, W. R. P., acting asst.-surgeon, granted 30 days' leave of absence from Nov. 23, 1908, 9 days with pay, and 23 days without pay.

BOARD CONVENED.

Board of medical officers convened to meet at the bureau, Nov. 23, 1908, for the purpose of making final revision of the regulations for the medical *examination of arriving aliens*. Assistant-Surgeon General H. D. Geddings, chairman; Surgeon George W. Stoner, Passed Assistant Surgeon J. W. Schereschewsky, Acting Assistant Surgeon, M. V. Safford, recorder.

Health Reports.

The *following* cases of *smallpox*, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, *during* the week ended Nov. 20, 1908:

SMALLPOX—UNITED STATES.

Arkansas: Sulphur Rock, Aug. 25-Nov. 9, 14 cases.

California: Cedarville, July 18-Nov. 6, 5 cases; San Francisco, Oct. 18-31, 19 cases.

District of Columbia: Washington, Oct. 24-31, 7 cases.

Illinois: Springfield, Oct. 22-29, 2 cases.

Indiana: Elkhart, Oct. 24-31, 3 cases; Lafayette, Oct. 26-Nov. 2, 4 cases; Terre Haute, Oct. 31-Nov. 7, 1 case.

Kansas: Topeka, Oct. 13-24, 1 case.

Kentucky: Covington, Oct. 24-Nov. 7, 2 cases.

Maine: Canadian Border, Nov. 8, 12 cases.

Montana: Butte, Oct. 20-27, 4 cases.

Ohio: Cincinnati, Oct. 23-30, 1 case.

Tennessee: Nashville, Oct. 24-31, 1 case; Stanton and vicinity, Sept. 10-Nov. 9, 21 cases.

Washington: Spokane, Oct. 24-31, 3 cases; Tacoma, Oct. 18-25, 1 case.
Washington: Spokane, e. 9mfwyp amfwy amfwy acmfwyp
Wisconsin: Manitowoc, Oct. 24-31, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Sept. 19-Oct. 3, 5 cases, 1 death.

SMALLPOX—FOREIGN.

Arabia: Aden, Oct. 12-19, 15 deaths.
Ceylon: Colombo, Sept. 19-Oct. 3, 38 cases, 10 deaths.
India: Bombay, Oct. 6-13, 2 deaths; Calcutta, Sept. 12-26, 4 deaths.
Indo-China: Saigon, Sept. 19-26, 2 cases.
Italy: General, Oct. 23-29, 14 cases; Naples, Oct. 17-24, 4 cases.
Mexico: Veracruz, Oct. 24, 1 case.
Peru: Lima, Oct. 19, 8 in lazaretto.
Russia: Moscow, Oct. 10-17, 9 cases, 2 deaths; St. Petersburg, Sept. 26-Oct. 10, 14 cases, 4 deaths.
Spain: Valencia, Oct. 17-24, 2 cases; Vigo, 1 death.
Zanzibar: Zanzibar, Sept. 14-21, 1 death.

YELLOW FEVER.

Brazil: Manaos, Sept. 26-Oct. 3, 2 deaths.
Ecuador: Guayaquil, Oct. 3-10, 1 death.
Mexico, Veracruz, Oct. 27, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Manila, Sept. 19-26, 314 cases, 184 deaths; Sept. 26-Oct. 3, 67 cases, 33 deaths; Provinces, Sept. 19-26, 1,122 cases, 745 deaths; Sept. 26-Oct. 3, 1,666 cases, 977 deaths.

CHOLERA—FOREIGN.

Ceylon: Colombo, Sept. 19-26, 2 cases.
China: Shanghai, Oct. 13, present.
India: Calcutta, Sept. 12-26, 13 deaths; Rangoon, Sept. 26-Oct. 3, 5 deaths.
Indo-China: Cholen, Sept. 19-26, 7 cases, 7 deaths.
Japan: Moji, Oct. 22, present.
Russia: St. Petersburg, Oct. 27-Nov. 2, 142 cases, 80 deaths.

PLAGUE.

Brazil: Maranhao, Oct. 20, present.
Chile: Iquique, Oct. 6, 1 case in lazaretto.
Ecuador: Guayaquil, Oct. 3-10, 1 death.
India: General, Sept. 19-26, 3,033 cases, 2,162 deaths; Bombay, Oct. 3-13, 10 deaths; Calcutta, Sept. 12-26, 12 deaths; Rangoon, Sept. 26-Oct. 3, 2 deaths.
Indo-China: Cholen, Sept. 19-26, 9 cases, 8 deaths; Saigon, 12 cases, 9 deaths.
Peru: General, Sept. 29-Oct. 7, 28 cases, 16 deaths; Callao, 1 case, 1 death.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

CALOMEL WITH LEMONADE AND WITH CHLORIN.

ROANOKE, VA., Nov. 14, 1908.

To the Editor:—1. Is there any danger in prescribing calomel and lemonade simultaneously? 2. Is there any danger in giving calomel and chlorin water simultaneously? JAMES H. DEYERLE.

ANSWER.—1. Calomel is acted on very slowly by non-oxidizing acids, so there need be no fear of an injurious result, under ordinary conditions, from the administration of lemon juice and of calomel.

2. Chlorin water is an oxidizing agent and converts calomel into corrosive sublimate by the addition of chlorin. $HgCl + Cl = HgCl_2$. There is, therefore, considerable danger that the calomel will be changed into poisonous corrosive sublimate (mercuric chlorid) if chlorin water is given at the same time.

SPIROCHETES IN THE LUNGS.

ROSEDALE, MISS., Nov. 8, 1908.

To the Editor:—Please inform me if there are any reports of cases of spirochetal infection of the lungs.

WILLIAM B. JOHNSON.

ANSWER.—There are, of course, no recorded cases of chancre of the lungs, so there are no reports of primary infection of the lungs with the *Spirochæta pallida*. So far as we know, there are no reports of the finding of spirochetes in gummata of the lungs in acquired syphilis. Syphilitic lesions in the lungs are very uncommon and it is also difficult to find spirochetes in gummata. They are, however, occasionally found in gummata and there is no reason why they should not be found in gummata of the lung. In congenital syphilis the spirochetes have been found repeatedly in the lungs. In Hoffman's "Atlas," Plate 21, Figures 1, 2 and 3 show spirochetes in the lung of a subject of congenital syphilis.

MEDICINAL ACTION OF CHROMIUM SULPHATE.

PHILADELPHIA, Nov. 12, 1908.

To the Editor:—Please tell through the columns of THE JOURNAL, what, if any, medicinal action chromium sulphate has. R. T. D.

ANSWER.—Most authorities do not mention the chromium salts or else state that they are not used in medicine. Experimental evidence regarding the pharmacologic action appears to be lacking. L. Kolipinski (*Month. Cycl. and Med. Bull.*, September, 1908) in a recent article makes the statement, which he says is unconfirmed by others, that chromium sulphate is not poisonous and may be given in doses of eight grains three times a day. He has observed no unpleasant by-effects. He claims to have used it with success in various affections, and makes the remarkable statement that locomotor ataxia is curable by the drug. In view of the actively poisonous character of the chromates it is advisable to use even chromium sulphate with caution.

INDIGO-CARMINE AND METHYLENE-BLUE TESTS FOR KIDNEY FUNCTION.

KANSAS CITY, MO., Nov. 12, 1908.

To the Editor:—Has THE JOURNAL described the technic of the methylene-blue test of Achard and the indigo-carmine test of Voelcker and Joseph for ascertaining the functional activity of the kidneys? B. CLARK HYDE.

ANSWER.—The indigo-carmine test is described in THE JOURNAL, Jan. 2, 1904, xlii, 69, in an abstract of an article by F. Voelcker and E. Joseph (*München. med. Wchnschr.*, l, No. 48). It consists essentially of introducing hypodermically 4 c.c. of a 4 per cent. solution of indigo-carmine and observing through the cystoscope the excretion of blue urine from one or both ureters; or the ureters may be catheterized and the urine from each collected separately. Kapsammer prefers the latter method. The methylene-blue method consists in the hypodermic injection of from 0.02 gm. to 0.05 gm. of methylene-blue. The excretion will begin in fifteen or twenty minutes in normal cases. Achard and Castaigne (*Bull. et mem. Soc. méd. d. hôp. d. Paris,* 1897, series 3, xiv, 1128) recommend the larger quantity, but Kapsammer prefers the smaller. For a full discussion of the subject see Kapsammer, "Nierendiagnostik und Nierenchirurgie," Part I, Vienna and Leipsic, 1907.

KERATINIZED CAPSULES OF IPECAC.

BRAINERD, MINN., Nov. 12, 1908.

To the Editor:—In the *Archives of Internal Medicine,* June, 1908, in an article on "Early Diagnosis and Treatment of the Presuppurative Stage of Amebic Hepatitis," Dr. Leonard Rogers of Calcutta, India, recommends the administration of ipecac in keratinized capsules. This method appealed strongly to me. During the past two months I have added "keratinized" capsules to our monthly hospital requisition, but each time reply has come back that the desired capsules could not be obtained. Can you give me the address of some dealer who handles them?

C. F. KARSHNER, M.D.

ANSWER.—We have been unable to learn that keratinized capsules are on the market. Pharmaceutical manuals, however, give methods by which any competent pharmacist may easily coat pills with keratin. In brief, the process consists in making a solution of keratin (preferably the variety of keratin which has been treated with pepsin to free it from pepsin-soluble material, and which is sold as pepsinized keratin) either in dilute acids if the pill mass resists the action of acids or in a weak alcoholic solution of ammonia if the pill mass resists alkalies. The pills are then given several coatings of this keratin solution. The following directions for the coating of pills with keratin are taken from "Prescription Practice and General Dispensing," by J. H. Beal, pages 125-126:

"To coat pills with keratin, a solution of the substance is made by heating it with a mixture of equal parts of ammonia water and dilute alcohol, or with dilute acetic acid, sprinkling the pills with the solution and rolling them in a porcelain capsule and drying. From eight to ten applications must be made to render the coating effective. The pills must not be made with an aqueous excipient, or they will contract and the coating crack. Cacao butter, or a mixture of cacao butter and yellow wax should be used. The conspergent should be either dry kaolin or powdered charcoal, and not a vegetable powder."

THE PARAFFIN IN THE BISMUTH PASTE.

WAKEFIELD, NEBR., Nov. 12, 1908.

To the Editor:—In the article on "Bismuth Treatment of Sinuses," in THE JOURNAL, March 14, 1908, p. 868, appears the following "Formula of Paste for Late Treatment:"

	gm.
Bismuth subnitrate	30
White wax	..
Soft paraffin āā	5
Vaselin	60

According to the U. S. Dispensatory, soft paraffin, petrolatum molle and vaselin are identical preparations. Still it is evident *that soft paraffin in the above formula refers to some other preparation than vaselin.* Kindly inform me what preparation of paraffin is intended.

A. E. ENGZELIUS.

Answer.—Petrolatum, also called vaselin, is a semi-solid substance, a product of petroleum deodorized, and produced after the lighter oils have been distilled off. Paraffin is a wax which is obtained by pressing the oil and has a much higher degree of hardness. The various grades of paraffin differ only in their degree of hardness, the melting points ranging from 90 to 140 degrees F. Dr. Beck states that he uses a paraffin which has a melting point of 120 degrees F. The addition of this paraffin in formula No. 2 is for the purpose of obtaining a firmer paste (one that will not melt at body temperature), which will occlude fistulous tracts and be retained in them as long as the body temperature remains normal.

PHENOLPHTHALEIN.

————, Conn., Nov. 2, 1908.

To the Editor:—Please discuss phenolphthalein, its physiologic action on the bowels, its dosage, and the best method of administration.

W. H. Y.

Answer.—A full account of the properties and action of phenolphthalein was published in this department, March 30, 1907. It is also described in "New and Nonofficial Remedies," a copy of which will be sent on receipt of 6 cents. This drug must be considered as one of the valuable contributions of chemical industry, and its importance justifies a recapitulation of our knowledge regarding it.

Phenolphthalein is a yellowish, tasteless powder, slightly soluble in water, readily soluble in alcohol and in aqueous solutions of hydroxids and carbonates. The investigations of Vamossy, Dornblüth, Tunnicliffe and others indicate that it is a safe cathartic, acting without pain in from four to six hours and leaving less tendency to sluggishness of the bowels as an after-effect than most cathartics. So far as our present knowledge goes it produces no noticeable physiologic effect except that of a purgative. When absorbed it is excreted in the urine generally unchanged in chemical character, but sometimes in combination so that its characteristic color with alkalies is only shown after the combination is broken up by heating with an acid. So far as known it does not irritate the kidneys. While overdoses may produce toxic effects by hypercatharsis no fatal case of poisoning has been reported. In one case mild toxic effects followed a dose of 1 gm. (15 grains). The dose generally recommended varies from 0.06 gm. (1 grain) to 0.3 gm. (5 grains), but it must be borne in mind that certain individuals possess a marked idiosyncrasy to phenol compounds and that in such cases phenolphthalein should be prescribed at first with caution. In most cases a dose of 0.13 gm. (2 grains) is well borne and frequently is ample. It may be given with safety in doses of 0.5 gm. (7¼ grains) and these doses seem to be necessary to secure its effect in bedridden patients or in obstinate cases. It is best given in the form of powders, capsules, pills or tablets. For example:

gm.
℞
Phenolphthalein ....4 | or ʒi
Div. in capsules vel pulveres No. xx.
Sig.: One capsule or powder at bedtime when necessary.

CHROMATIC ABERRATION.

Philadelphia, Nov. 3, 1908.

To the Editor:—While crossing a railroad track this evening, I observed what was to me a very interesting ocular phenomenon. It may be well known to oculists, but I do not recall mention of it in any text-book. The phenomenon was as follows: About fifty yards away I saw a purple signal light surrounded by a blue radiation. I have a considerable degree of astigmatism and wear the usual correcting lens. I removed my glasses and the light appeared as a broad, horizontal line of bright red intersecting a vertical line of pure blue—the two primary colors, of course, which together form purple. I shall be glad of an explanation of the phenomenon.

H. L. Bates.

Answer.—Purple is composed of blue and red, which are refracted at different angles, so that they come to a focus at different distances from the cornea, the blue having a shorter focal distance than the red. In a normal eye the rays are mingled, as the focal distance of the retina is not exactly equal to that of either red or blue. In a myopic eye the red rays, having the longer focal distance, will reach the retina (which is placed at a greater distance from the cornea in the myopic eye than in the normal one), while the blue rays come to a clear focus only at the periphery of the fields of vision. Consequently, a person with myopia who looks at a purple light sees a red center surrounded by a blue ring. One who is hyperopic sees a blue center surrounded by a red ring. Our correspondent undoubtedly has some myopia in addition to his corrected astigmatism. When he removed his glasses the astigmatism came into play; and, as one or both eyes were shorter in the vertical than in the horizontal axis, the blue rays reached the retina in the vertical meridian and the red rays in the horizontal one. The property by which purple is thus analyzed by the eye is made use of in the chromatic aberration, or cobalt blue glass test. Cobalt blue is essentially a purple, which absorbs all light except red and blue. If such a glass is placed before an eye under the influence of a mydriatic, the following phenomena will be observed: 1. The normal eye perceives a purple spot. 2. The hyperopic eye perceives a red ring with a blue center. 3 The myopic eye perceives a blue ring with a red center. 4. An astigmatic eye perceives various other arrangements of blue and red. Descriptions of this test may be found in "Refraction of the Eye," (p. 126) by Ernest Clarke, published by William Wood & Co., and in "Refraction and How to Refract" (ed. 2, p. 143), by James Thorington, published by P. Blakiston's Son & Co., as well as in other works on ophthalmology.

Medical Education and State Boards of Registration

COMING EXAMINATIONS.

California: Los Angeles, Dec. 1. Sec'y., Dr. Charles L. Tisdale, Butler Bldg., San Francisco.
Delaware: Regular, Dover; Homeopathic, Wilmington, Dec. 8-10. Sec'y. of Medical Council, Dr. Henry W. Briggs, Wilmington.
Iowa: Capitol Building, Des Moines, Dec. 8-10. Sec'y., Dr. Louis A. Thomas.
Maryland: Baltimore, Dec. 8. Sec'y., Dr. J. McPherson Scott, Hagerstown.
Maryland: Homeopathic, Baltimore, Dec. 8. Sec'y., Dr. J. S. Garrison, 848 W. North Ave., Baltimore.
New Hampshire: Concord, Dec. 29-30. Regent, Mr. H. C. Morrison.
Ohio: Columbus, Dec. 8-10. Sec'y. Dr. George H. Matson.
Pennsylvania: Musical Fund Hall, Locust St., Philadelphia, Dec. 1-4. Sec'y. of Medical Council, Dr. N. C. Schaeffer, Harrisburg.
Virginia: Lynchburg, Dec. 15-18. Sec'y., Dr. R. S. Martin, Stuart.

Work for a Standard Curriculum in Medical Colleges.

During the present period of reconstruction in medical colleges, probably no work is more important than that of preparing a standard medical curriculum which is based on an exhaustive study of present conditions and the requirements of modern medicine. Without such a standard there is danger that by some colleges too much stress may be laid on preliminary education, others may over-develop the scientific fundamental branches, while others may emphasize too much the clinical side of medical teaching.

The ideal medical curriculum would be one not so overcrowded as to prevent the best work but one which would furnish the best training and equipment for practitioners in medicine. So extensive has become the domain of medical knowledge that it is necessary to point out clearly what subjects should be required and what should be electives. Of the required subjects it should also be stated how much emphasis should be laid on each.

Among the electives would naturally come many of the courses on the specialties; laryngology, rhinology, ophthalmology, otology, etc., although a certain knowledge of all these subjects is necessary to every general practitioner. Among the specialties of modern medicine might well be included the positions of laboratory instructors which now demand men who are experts in their particular subjects. Such courses and research work as are intended to prepare men for these positions would naturally come among the electives and not in the required courses.

With the object of securing a standard curriculum the Council on Medical Education decided to ask the cooperation of a large number of educators representing every phase of the subject. A committee of one hundred, therefore, has been appointed which is divided into ten subcommittees, each subcommittee to cover a certain division of the curriculum. These subcommittees are now actively at work, and it is expected that the complete report will be presented at the next conference of the Council, April 5, 1909.

The following constitutes the personnel of the committee:

SECTION 1.—ANATOMY, INCLUDING HISTOLOGY AND EMBRYOLOGY.

Chairman: Charles R. Bardeen, M.D., Professor of Anatomy, University of Wisconsin, College of Medicine, Madison, Wis.

Albert C. Eycleshymer, Ph.D., Professor and Director of the Department of Anatomy, Histology and Embryology, St. Louis University, Grand Ave. and Carolina St., St. Louis.

Irving Hardesty, Ph.D., Assistant Professor of Anatomy, University of California, Medical Department, San Francisco.

G. Carl Huber, M.D., Professor of Histology and Embryology, University of Michigan, College of Medicine, 1330 Hill St., Ann Arbor, Mich.

George S. Huntington, M.D., Professor of Anatomy, Columbia University, 437 W. 59th St., New York City.

Clarence M. Jackson, M.D., Professor of Anatomy and Histology, University of Missouri, Medical Department, Columbia.

Thomas G. Lee, M.D., Professor of Histology and Embryology, University of Minnesota, College of Medicine and Surgery, 509 St. Anthony Parkway, S.E., Minneapolis.

Franklin P. Mall, M.D., Professor of Anatomy, Johns Hopkins University, Medical Department, 1514 Bottom St., Baltimore.

James P. McMurrich, Ph.D., Professor of Anatomy, University of Toronto, Medical Department, 576 Huron St., Toronto, Canada.

George A. Piersol, M.D., Professor of Anatomy, University of Pennsylvania, Department of Medicine, 4724 Chester Ave., Philadelphia.

SECTION 2.—PHYSIOLOGY AND PHYSIOLOGIC CHEMISTRY.

Chairman: Elias P. Lyon, Ph.D., Professor of Physiology, St. Louis University, School of Medicine, St. Louis.

Percy M. Dawson, M.D., Associate Professor of Physiology, Johns Hopkins University, Medical Department, Baltimore.

Otto Folin, Ph.D., Professor of Biologic Chemistry, Harvard Medical School, Longwood Ave., Boston.

Walter E. Garrey, Ph.D., Professor of Physiologic Chemistry, Cooper Medical College, San Francisco.

Winfield Scott Hall, M.D., Professor of Physiology, Northwestern University Medical School, 2431 Dearborn St., Chicago.

Frederic S. Lee, Ph.D., Professor of Physiology, Columbia University, College of Physicians and Surgeons, New York City.

Warren P. Lombard, M.D., Professor of Physiology, University of Michigan, College of Medicine, 805 Oxford Road, Ann Arbor, Mich.

Graham Lusk, Ph.D., Professor of Physiology, University and Bellevue Hospital Medical College, 338 E. 26th St., New York City.

Gustav Mann, M.D., Professor of Physiologic Chemistry, Tulane University of Louisiana, New Orleans.

Albert P. Mathews, Ph.D., Professor of Physiologic Chemistry, University of Chicago.

SECTION 3.—PATHOLOGY AND BACTERIOLOGY.

Chairman: William T. Councilman, M.D., Professor of Pathology, Harvard Medical School, 240 Longwood Ave., Boston.

J. G. Adami, M.D., Professor of Pathology, McGill University, Medical Department, Montreal, Canada.

W. M. L. Coplin, M.D., Professor of Pathology and Bacteriology, Jefferson Medical College, Tenth and Walnut Sts., Philadelphia.

Harold C. Ernst, M.D., Professor of Bacteriology, Harvard Medical School, 240 Longwood Ave., Boston.

James Ewing, M.D., Professor of Pathology, Cornell University Medical College, 256 W. 57th St., New York City.

Ludwig Hektoen, M.D., Professor and Head of the Department of Pathology, Rush Medical College, 5803 Washington Ave., Hyde Park, Chicago.

William T. Howard, M.D., Professor of Pathology, Pathological Anatomy and Bacteriology, Western Reserve University, 1838 E. 65th St., Cleveland, Ohio.

Richard M. Pearce, M.D., Professor of Pathology and Bacteriology, University and Bellevue Hospital Medical College, 338 East 26th St., New York City.

Aldred S. Warthin, M.D., Professor of Pathology, University of Michigan, College of Medicine and Surgery, 924 Baldwin Ave., Ann Arbor, Mich.

William H. Welch, M.D., Baxley Professor of Pathology, Johns Hopkins Medical School, 807 St. Paul St., Baltimore.

SECTION 4.—PHARMACOLOGY, TOXICOLOGY AND THERAPEUTICS.

Chairman: Torald Sollmann, M.D., Professor of Pharmacology and Materia Medica, Pharmacologic Laboratory, Western Reserve University Medical Department, Cleveland, Ohio.

John J. Abel, M.D., Professor of Pharmacology, Johns Hopkins University Medical School, Charles St. Ave., (P. O. Sta. L.) Baltimore.

Joseph A. Capps, M.D., Assistant Professor of Medicine, Rush Medical College, University of Chicago, 100 State St., Chicago.

David L. Edsall, M.D., Assistant Professor of Medicine, University of Pennsylvania, Medical Department, 1432 Pine St., Philadelphia.

Charles Wallis Edmunds, M.D., Junior Professor of Therapeutics and Materia Medica, University of Michigan, College of Medicine, 520 East Ann St., Ann Arbor, Mich.

John Taylor Halsey, M.D., Professor of Materia Medica, Therapeutics and Clinical Medicine, Tulane University of Louisiana, 124 Baronne St., New Orleans.

Egbert LeFevre, M.D., Professor of Therapeutics and Clinical Medicine, University and Bellevue Hospital Medical College, 52 West 56th St., New York City.

Eli H. Long, M.D., Professor of Materia Medica and Therapeutics, University of Buffalo, Medical Department, Buffalo, N. Y.

William DeBerniere MacNider, M.D., Professor of Pharmacology and Bacteriology, University of North Carolina, Chapel Hill.

Oliver Thomas Osborne, M.D., Professor of Materia Medica and Therapeutics, and Clinical Professor of Medicine, Yale Medical School, 252 York St., New Haven, Conn.

SECTION 5.—MEDICINE, INCLUDING PEDIATRICS AND NERVOUS AND MENTAL DISEASES.

Chairman: George Dock, M.D., Professor of Medicine, Tulane University of Louisiana, 124 Baronne St., New Orleans.

George Blumer, M.D., Professor of the Theory and Practice of Medicine, Yale Medical School, New Haven, Conn.

William Fitch Cheney, M.D., Professor of Principles and Practice of Medicine, Cooper Medical College, Shreve Bldg., San Francisco.

Henry A. Christian, M.D., Professor of the Theory and Practice of Physic, Harvard Medical School, 252 Marlboro St., Boston.

F. X. Dercum, M.D., Professor of Nervous and Mental Diseases, Jefferson Medical College, 1719 Walnut St., Philadelphia.

Frederick Forchheimer, M.D., Professor of Theory and Practice of Medicine and Clinical Medicine, Medical College of Ohio, Cincinnati.

Charles L. Greene, M.D., Professor of Medicine, University of Minnesota, College of Medicine and Surgery, Minneapolis.

L. Emmett Holt, M.D., Carpentier Professor of the Diseases of Children, Columbia University, College of Physicians and Surgeons, 14 W. 55th St., New York City.

John H. Musser, M.D., Professor of Clinical Medicine, University of Pennsylvania, Medical Department, Philadelphia.

W. Gilman Thompson, M.D., Professor of Medicine, Cornell University, Medical College, 34 E. 31st St., New York City.

SECTION 6.—SURGERY; GENERAL AND SPECIAL.

Chairman: Charles H. Frazier, M.D., Professor of Clinical Surgery, University of Pennsylvania, Department of Medicine, 1724 Spruce St., Philadelphia.

Dudley Peter Allen, M.D., Professor of the Theory and Practice of Surgery and Clinical Surgery, Western Reserve University, Medical Department, 1110 Euclid Ave., Cleveland, Ohio.

Joseph A. Blake, M.D., Professor of Surgery, Columbia University, College of Physicians and Surgeons, 601 Madison Ave., New York City.

Herbert L. Burrell, M.D., Professor of Clinical Surgery, Harvard Medical School, 22 Newbury St., Boston.

Frederick Henry Gerrish, M.D., Professor of Surgery, Medical School of Maine, 675 Congress St., Portland, Me.

William S. Halsted, M.D., Professor of Surgery, Johns Hopkins University, Medical School, Baltimore.

Rudolph Matas, M.D., Professor of General and Clinical Surgery, Tulane University of Louisiana, 2255 St. Charles Ave., New Orleans.

Lewis S. McMurtry, M.D., Professor of Abdominal Surgery and Gynecology, University of Louisville, Medical Department, The Atherton, Fourth and Chestnut Sts., Louisville, Ky.

William L. Rodman, M.D., Professor of the Principles of Surgery and Clinical Surgery, Medico-Chirurgical College, 1904 Chestnut St., Philadelphia.

Harry M. Sherman, M.D., Professor of the Principles and Practice of Surgery, University of California, Medical Department, 2210 Jackson St., San Francisco.

SECTION 7.—OBSTETRICS AND GYNECOLOGY.

Chairman: Joseph B. DeLee, M.D., Professor of Obstetrics, Northwestern University Medical School, 810-34 Washington St., Chicago.

John G. Clark, M.D., Professor of Gynecology, University of Pennsylvania, Department of Medicine, 2017 Walnut St., Philadelphia.

Edwin B. Cragin, M.D., Professor of Obstetrics and Gynecology, Columbia University College of P. and S., 10 W. 50th St., New York City.

J. Clifton Edgar, M.D., Professor of Obstetrics, Cornell University Medical College, 50 E. 34th St., New York City.

Charles M. Green, M.D., Professor of Obstetrics, Harvard Medical School, 78 Marlborough St., Boston.

James R. Guthrie, M.D., Professor of Obstetrics and Gynecology, State University of Iowa, Medical Department, 1005 Locust St., Dubuque, Iowa.

Ernest S. Lewis, M.D., Professor of Obstetrics and Gynecology, Tulane University of Louisiana, 124 Baronne St., New Orleans.

Reuben Peterson, M.D., Professor of Obstetrics, University of Michigan, College of Medicine, 620 Forest Ave., Ann Arbor, Mich.

Henry Schwartz, M.D., Professor of Obstetrics and Gynecology, Washington University, Medical Department, St. Louis.

J. Whitridge Williams, M.D., Professor of Obstetrics, Johns Hopkins University Medical School, 1128 Cathedral St., Baltimore.

SECTION 8.—DISEASES OF THE EYE, EAR, NOSE AND THROAT.

Chairman: George E. deSchweinitz, M.D., Professor of Ophthalmology, University of Pennsylvania, Department of Medicine, 1705 Walnut St., Philadelphia.

Diseases of the Eye.

Edward Jackson, M.D., Professor of Ophthalmology, University of Colorado, School of Medicine, 1434 Glenarm St., Denver.

Myles Standish, M.D., Assistant Professor of Ophthalmology, Harvard Medical School, 256 Newbury St., Boston.

William H. Wilder, M.D., Professor and Head of the Department of Ophthalmology, University of Chicago, 103 State St., Chicago.

Diseases of the Ear.

Clarence John Blake, M.D., Professor of Otology, Harvard Medical School, 226 Marlboro St., Boston.

B. Alexander Randall, M.D., Clinical Professor of Diseases of the Ear, University of Pennsylvania, Department of Medicine, 1717 Locust St., Philadelphia.

Frank C. Todd, M.D., Professor of Ophthalmology and Otology, University of Minnesota, College of Medicine, 304 Pillsbury Bldg., Minneapolis.

Diseases of the Nose and Throat.

Cornelius G. Coakley, M.D., Professor of Laryngology, University and Bellevue Hospital Medical College, 53 W. 56th St., New York City.

D. Braden Kyle, M.D., Professor of Laryngology, Jefferson Medical College, 1517 Walnut St., Philadelphia.

John N. MacKenzie, M.D., Clinical Professor of Laryngology and Rhinology, Johns Hopkins Medical School, 879 Park Ave., Baltimore.

SECTION 9.—DERMATOLOGY AND VENEREAL DISEASES.

Chairman: William A. Pusey, M.D., Professor of Dermatology and Clinical Dermatology, College of Physicians and Surgeons, 72 Madison St., Chicago.

John T. Bowen, M.D., Edward Wigglesworth Professor of Dermatology, Harvard Medical School, 14 Marlboro St., Boston.

William T. Corlett, M.D., Professor of Dermatology and Syphilology, Western Reserve University, Medical Department, 1935 Euclid Ave., Cleveland, Ohio.

Isadore Dyer, M.D., Professor of the Diseases of the Skin, Tulane University of Louisiana, New Orleans.

John A. Fordyce, M.D., Professor of Dermatology, University and Bellevue Hospital Medical College, 80 W. 40th St., New York City.

T. Casper Gilchrist, M.D., Clinical Professor of Dermatology, Johns Hopkins University Medical Department, 330 N. Charles St., Baltimore.

William A. Hardaway, M.D., Professor of Diseases of the Skin and Syphilis, Washington University, Medical Department, 4500 Olive St., St. Louis.

Milton B. Hartzell, M.D., Associate in Dermatology, University of Pennsylvania, Department of Medicine, 3644 Chestnut St., Philadelphia.

Douglass W. Montgomery, M.D., Professor of Diseases of the Skin, University of California, Medical Department, 2419 California St., San Francisco.

Grover W. Wende, M.D., Clinical Professor of Dermatology, University of Buffalo, Department of Medicine, 471 Delaware Ave., Buffalo, N. Y.

SECTION 10.—HYGIENE, MEDICAL JURISPRUDENCE AND MEDICAL ECONOMICS.

Chairman: F. F. Wesbrook, M.D., Professor of Pathology and Bacteriology, University of Minnesota, College of Medicine, Minneapolis.

Charles V. Chapin, M.D., Superintendent of Health, Providence, R. I.

Irving Fisher, Ph.D., Professor of Political Economy, Yale University, 460 Prospect St., New Haven, Conn.

John S. Fulton, M.D., Secretary-General, Sixth International Congress on Tuberculosis, 714 Colorado Bldg., Washington, D. C.

J. N. McCormack, M.D., Secretary Kentucky State Board of Health, Bowling Green, Ky.

C. O. Probst, M.D., Secretary Ohio State Board of Health, Columbus, Ohio.

M. P. Ravenel, M.D., Professor of Bacteriology, University of Wisconsin, Madison, Wis.

Franklin C. Robinson, A.M., Professor of Chemistry, Mineralogy and Natural Science, Bowdoin College, 214 Maine St., Brunswick, Me.

M. J. Rosenau, M.D., U. S. Public Health and Marine-Hospital Service, Washington, D. C.

Victor C. Vaughan, M.D., Professor of Hygiene and Physiologic Chemistry, University of Michigan, College of Medicine, Ann Arbor, Mich.

Massachusetts July and September Reports.

Dr. Edwin B. Harvey, secretary of the Board of Registration in Medicine, reports the written examinations held at Boston, July 14-16 and Sept. 8-10, 1908. The number of subjects examined was 13; total number of questions asked, 70; percentage required to pass, 75.

At the examination held July 14-16, the total number of candidates examined was 131, of whom 91 passed, including one non-graduate, and 40 failed, including 13 non-graduates. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Yale Med. School	(1908)	79.4, 80.6, 82.1
Medical School of Maine	(1904) 82; (1908)	79.1
University of Maryland	(1908)	79.3
College of P. and S., Baltimore	(1908)	75, 75, 77.5
Baltimore Med. Coll	(1907) 76.6; (1908)	75, 75, 79, 79.7
College of P. and S., Boston	(1908)	75, 75, 76.4, 82.4
Harvard Med. School	(1895) 80.3; (1907) 75.4, 76.7; (1908)	75, 75, 75.2, 76.7, 77.3, 78.1, 78.3, 80.1, 80.2, 80.6, 81.2, 81.5, 81.5, 82.4, 83.5, 86.
Boston University	(1908)	75, 75, 75.2, 76.2, 76.3, 76.3, 76.9, 77.7, 78.5, 79.7, 80.2, 81.1, 83.
Tufts Coll. Med. School	(1907) 76.2, 80; (1908)	75, 75, 75, 75, 75, 75.2, 75.5, 75.5, 75.8, 766.2, 76.2, 76.3, 76.5, 76.5, 76.6, 76.6, 76.7, 76.9, 78, 78.6, 78.7, 78.7, 78.7, 78.8, 78.8, 79.6, 81.2, 81.3, 83.2.
University of Minnesota	(1901)	78.2
College of P and S., New York	(1905)	78.3
University and Bellevue Hosp. Med. Coll.	(1900) 77; (1907)	76
New York Homeo. Med. Coll	(1905)	81.4
Western Reserve University	(1905)	80.6
Jefferson Med. Coll	(1908)	75, 81.3
University of Vermont	(1908)	77.1

FAILED.

College.	Year Grad.	Per Cent.
George Washington University	(1907)	71.7
Georgetown University	(1906)	71.7
Maryland Med. Coll	(1908)	60
Boston University	(1908)	54.5, 68.7
Baltimore Med. Coll.	(1905) 62.4; (1907) 67.6, 71.7; (1908)	60.9, 61.1, 69, 69.7, 71, 72.4.
Baltimore University	(1895)	36
College of P. and S., Boston	(1905) 63.5; (1908)	65.3, 66, 68.7
Tufts Coll. Med. School	(1908)	67, 72
North Carolina Med. Coll	(1904)	69.9
University of Vermont	(1906)	70.5
Laval University, Quebec	(1905)* (1908)	67.6
Imperial Alexanders Univ., Finland	(1902)	58.4
University of Naples, Italy	(1906)	67.5

At the examination held September 8-10, the total number of candidates examined was 65, of whom 35 passed, including one non-graduate and 30 passed, including 2 non-graduates. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
George Washington University	(1907)	75
Georgetown University	(1905)	77.1

Marriages

Ira M. Miller, M.D., to Miss Alice A. Starke, both of Chicago, October 21.

Alfred Ullman, M.D., Baltimore, to Miss Bertha Katz, at Philadelphia, November 12.

Daniel M. Kelly, M.D., Baraboo, Wis., to Miss O'Brien of Harvard, Ill., November 18.

G. B. Sims, M.D., Hastings, Neb., to Miss Olga Jacobsen, of Edgewater, Chicago, November 3.

Louis W. Eckles, Jr., M.D., Louisville, to Miss Glenna Lee Sells, of Anderson, Ind., November 11.

Charles M. Scott, M.D., Bluefield, W. Va., to Miss Hazel Morton, of Ashland, Ky., November 10.

Elliston J. Morris, M.D., Philadelphia, to Miss Josephine C. Mitchell, of New York City, November 11.

John Glenn Young, M.D., Pontiac Ill., to Miss Floy Martha Reynolds, of Genoa Junction, Wis., October 28.

Dennis A. Bethea, M.D., Terre Haute, Ind., to Miss Alice Blackman McLeod, of Dillon, S. C., November 11.

Josephus Tucker Ullom, M.D., Germantown, Philadelphia, to Miss Selena P. Hughes, at Philadelphia, October 15.

Ernest Leroy Bolton, M.D., to Miss Maude Mary Luce, both of Chilton, Wis., at Kewaunee, Wis., November 12.

Deaths

Thomas M. Wilson, M.D. Rush Medical College, 1906; a B.Sc. of the University of Toronto; and about to receive the degree of Ph.D. from the University of Chicago; an interne in the Presbyterian Hospital and instructor in pathology in the Chicago Veterinary College; who had devoted all his leisure for a year past to experiments in the laboratories of the McCormick Memorial Institute in an attempt to produce a serum to counteract the effect of the bacillus of glanders; died November 19, in the Presbyterian Hospital, from glanders, after an illness of three weeks, aged 38, a martyr in the cause of scientific research.

Adoniram Judson Gibbs, M.D. Pennsylvania Medical College, Gettysburg, 1857; a member of the American Medical Association; city physician and a member and formerly president of the board of health of Denison, Texas, and Eureka Springs, Ark.; formerly president of the Denison (Texas) and Eureka Springs and Carroll County (Ark.) Medical Society; surgeon in the Confederate service during the Civil War; formerly editor of the *Eureka Springs Medical Journal;* died at his home in Denison, November 12, aged 72.

Elihu T. Mendenhall, M.D. Medical College of Ohio, 1877; a member of the Indiana State Medical Association; a veteran of the Civil War; for two terms a member of the city council of New Castle, Ind.; for many years health officer of Henry county, and secretary of the local board of U. S. pension examining surgeons; died at Mechanicsburg, Ind., November 14, from disease of the stomach, aged 64.

Charles M. Gravis, M.D. Medical College of Indiana, Indianapolis, 1871; a member of the Indiana State Medical Association; a veteran of the Civil War; and treasurer of the local board of U. S. pension examining surgeons; medical director of Highland Sanitarium, Martinsville; died at his home in that city, November 11, from cerebral hemorrhage, aged 63.

Mark P. Perry, M.D. College of Physicians and Surgeons, Baltimore, 1884; formerly of Macon, N. C.; a member of the Medical Society of the State of North Carolina, and for six years its treasurer; the head of a hospital in Richwood, W. Va.; died in Johns Hopkins Hospital, Baltimore, November 9, aged 40.

Lyman R. Farr, M.D. Chicago Medical College, 1884; a member of the State Medical Society of Wisconsin; visiting physician to St. Mary's and the Strong Emergency hospitals, Beloit, Wis.; for a long time city physician of Beloit; died at his home November 12, from edema of the glottis, aged 46.

William Henry Long, Jr., M.D. College of Physicians and Surgeons, New York City, 1898; a member of the Medical Society of New Jersey; surgeon to the Somerset County Hospital and coroner and physician to Somerset county; died at his home in Somerville, May 20, aged 31.

Thomas J. Lipscomb, M.D. Medical College of the State of South Carolina, Charleston, 1857; a Confederate veteran; superintendent of the state penitentiary, Newberry, from 1878 to 1890; mayor of Newberry in 1898; died at his home in Columbia, S. C., November 4, aged 75.

Alonzo Pettit, M.D. University of Buffalo, N. Y., 1867; a member of the American Medical Association; one of the organizers of, and consulting surgeon, to the Elizabeth (N. J.) General Hospital; died at his home in Elizabeth, November 14, from heart disease, aged 66.

Charles Smith Boynton, M.D. Medical School of Maine, Brunswick, 1864; of Burlington, Vt.; adjunct professor of chemistry in the University of Vermont from 1890 to 1898; fell down an elevator shaft in Burlington, November 14, and was instantly killed, aged 72.

James E. Stanton, M.D. College of Physicians and Surgeons, Keokuk, 1872; a member of the Iowa State Medical Society; for more than fifty years a practitioner of Ohio and Chariton, Iowa; died at his home in Chariton, November 6, from cerebral hemorrhage, aged 80.

Levi Saunders, M.D. Harvard Medical School, Boston, 1857; common councilman of Gloucester in 1876 and alderman in 1877 and 1878; from 1879 to 1887 a member of the school committee; died at his home in Lanesville, Gloucester, Mass., November 11, aged 83.

Lucy M. Warner, M.D. Womans Medical College of Pennsylvania, Philadelphia, 1905; a member of the attending staff of the Wisconsin Northern Hospital for the Insane, Winnebago; died suddenly in that institution, November 11, from heart disease, aged 26.

Herman Cooper, M.D. Dartmouth Medical School, Hanover, N. H., 1883; a member of the American Medical Association; died at his home in Amesbury, Mass., from thrombosis of the pulmonary vein, and interstitial nephritis, November 10, aged 49.

Oliver W. Hatch (years of practice, Ind.); at one time secretary of the board of health of Elkhart; for more than half a century a practitioner of medicine; died at his home in Cassopolis, Mich., November 11, from pneumonia, aged 83.

William R. Schoonover, M.D. Kentucky School of Medicine, Louisville, 1876; of Warsaw, Ind.; physician to the Winona Assembly; died in the Northern Indiana State Hospital for the Insane, Longcliff, Logansport, November 12, aged 68.

Howard E. Gates, M.D. Long Island College Hospital, Brooklyn, 1861; a veteran of the Civil War, and for twenty-five years thereafter a practitioner of Litchfield, Conn.; died November 9, at his home in Colorado Springs, aged 69.

Samuel A. Mason, M.D. Memphis (Tenn.) Hospital Medical College, 1888; for thirty-three years a practitioner of Arkansas; shot and killed himself at his home in Hattiesville, November 9, while temporarily insane, aged 59.

Joseph Lavender Laxton, M.D. Washington University, Baltimore, 1868; a member of the Medical Society of North Carolina, and a Confederate veteran; died at his home in Morganton, November 11, from acute gastritis, aged 73.

Ogden Doremus King, M.D. Long Island College Hospital, Brooklyn, N. Y., 1884; a member of the Medical Society of the State of North Carolina; died at his home in Albemarle, November 11, from nephritis, aged 49.

George Corrie, M.D. Medical College of Virginia, Richmond, 1888; formerly of Back Bay, Va.; a member of the Medical Society of Virginia; died at his home in Knott's Island, N. C., October 10, from nephritis, aged 51.

Alexander Stilwell, M.D. University of Michigan, Ann Arbor, 1867; a member of the American Medical Association; since his graduation a practitioner of Dwaarkill, N. Y.; died at his home, November 7, aged 71.

Patrick Eugene Sullivan, M.D. College of Physicians and Surgeons, Boston, 1900; for six years ambulance surgeon of Lowell, Mass.; died at the home of his cousin in Lowell, November 10, aged 35.

Paul W. Kirkpatrick, M.D. Vanderbilt University, Nashville, 1893; of Alamogordo, N. M.; a member of the New Mexico Medical Association; died in Mexico from tuberculosis, November 7, aged about 40.

Charles Herbert Brereton, M.D. Medical Department Victoria College, Toronto, 1868; M.C.P.&S., Ont., 1868; of Bethany, Ont.; died at the home of his son in Carnduff, Sask., September 6, aged 63.

Riley Wiltshire Cavins, M.D. Indiana Medical College, Indianapolis, 1872; of Sterling, Kan.; died at the home of his mother in Bloomfield, Ind., April 30, from valvular heart disease, aged 62.

James R. Meeks, M.D. Starling Medical College, Columbus, Ohio, 1863; for many years a practitioner of Dallas; died at the home of his son in Kirkwood, St, Louis, November 9, aged 76.

David K. Bechtel, M.D. Howard University, Washington, D. C., 1879; of Kulpsville, Pa.; a patient in a private hospital in Philadelphia, was burned to death November 12, aged 63.

George W. Root, M.D. Cleveland Homeopathic Medical College, 1902; of Alliance, Ohio; was accidentally shot and killed while hunting near Birkendale, Ont., November 7, aged 27.

Rolla W. Bula, M.D. Philadelphia University of Medicine and Surgery, 1870; died at his home in Indianapolis, November 10, a year after a surgical operation, aged 60.

Alfred F. Griggs, M.D. Atlanta (Ga.) Medical College, 1895; formerly of Birmingham, Ala.; died at his home in Reno, Nev., November 9, from tuberculosis, aged 34.

Lewis Lamar, M.D. Starling Medical College, Columbus, Ohio, 1867; died at his home in Benevola, near Hagerstown, Md., November 12, from paralysis, aged 70.

George P. Boone, M.D. University of Louisville (Ky.), 1898; formerly of Beard, Ky.; died at his home in Colorado Springs, November 10, from tuberculosis, aged 32.

Anson Sprague, M.D. Botanico-Medical College of Ohio, Cincinnati, 1876; of Newville, Cal.; died in the Glenn County Hospital, Willows, Cal., recently, aged 78.

Joseph Weeks, M.D. Physio-Medical Institute, Cincinnati, 1861; died at his home in Mechanicsburg, Ind.; November 16, from heart disease, aged 88.

George Joel Henry, M.D. Hahnemann Medical College, Philadelphia, 1908; died suddenly at his home in Hanover, Pa., November 7, aged 26.

Edward Dodd, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1903; of Winnetoon, Neb.; died in Dansville, N. Y., April 27, aged 29.

Josiah E. Hawkins, M.D. Cincinnati College of Medicine and Surgery, 1872; died at his home in Bayou Chicot, La., October 22, aged 71.

Elliott L. Blackmore, M.D. Washington University, St. Louis, 1871; died at his home in Aplington, Iowa, recently, aged 66.

George O. Brown, M.D. Pulte Medical College, Cincinnati, 1886; died at his home in Georgetown, Ky., April 13, aged 67.

Luther Kimbell (license, Conn., 1893), of Norwich, Conn.; *died in a hospital in that city*, November 11, aged 75.

John B. C. Wright, M.D. Atlanta (Ga.) Medical College, 1866; of Elko, S. C.; died recently, aged 70.

Dr. F. C. Moor, Tallahassee, Fla.: My experience has been that in the cases in which the coal-tar drugs did good if they were omitted the temperature was not excessive anyway, and when the temperature was very high, very large doses had to be given and the depressing effect was very decided. In 90 per cent. of cases I believe that it is possible to carry out some form of hydrotherapy, and the strict Brand method is valuable in children.

Dr. J. A. Witherspoon, Nashville, Tenn.: I think we fail to take into consideration that typhoid is largely a self-limited infection, and I believe that all coal-tar derivatives and opium (except possibly in hemorrhage) are absolutely contraindicated. The principles of treatment in typhoid should be to conserve the patient's vitality and to eliminate the toxins, and any treatment that depresses and lowers temperature temporarily markedly decreases the vital forces and in my judgment is contraindicated.

Dr. H. M. Folkes, Biloxi, Miss: Out of some 140 cases of typhoid fever I have had but one case of perforation, and in that case there was sudden extreme pain. I would like to know to what extent that symptom has been observed.

Dr. W. S. Thayer, Baltimore: I think a blood count is very important at the time of perforation. It is impossible, however, for every practitioner to make a blood count, but I would lay stress on the importance, under such circumstances, of examining fresh specimens of the blood. I agree with Dr. Dock and Dr. Witherspoon regarding antipyretics. It is more than forty years now since the cold baths were first employed, and that method has produced an enormous change in the statistics of typhoid fever.

Dr. Thayer: I have not seen any relative increase in the polymorphonuclears in perforation. The leucocyte count is simply a straw in making the diagnosis of perforation, and can not be relied on alone. There is a great difference of opinion as to the use of morphin. I never use it except in hemorrhage. Especially when there is diarrhea with the hemorrhage, I think the lead and opium pills the best.

Dr. C. W. Strickler: I had the opportunity of watching Dr. Boeckh's series of cases. I took the blood pressure in one of the cases, and there was no lowering of blood pressure after the use of the aspirin. If we are going to use any of these preparations aspirin is probably the safest.

Dr. E. V. Boeckh, in closing: I was evidently misunderstood, as it was never my intention to put any drug ahead of hydrotherapy in typhoid. My only claim was, that it seemed from the cases observed when baths were contraindicated and in which it was necessary to give an antipyretic drug, that aspirin was the least harmful of any that we possess.

Prophylaxis of Malaria.

Dr. W. S. Thayer, Baltimore: We know the life history of the malarial parasite, and if its cycle could be broken at any one point malaria would be eradicated in that particular community. There are three ways of accomplishing this, namely, mosquito reduction, protection of individuals from mosquitoes, and the destruction of the parasites in the human host. The *Anopheles* breeds especially in marches, in shallow collections of water occurring under natural conditions, in ruts, in places which have been dug up in the ground. The problem of the removal of the breeding places of *Anopheles* mosquitoes means the thorough and complete drainage everywhere about the affected region, and the clearing up of all standing water. The use of oil on water where mosquitoes breed is at best only a makeshift, and not nearly so efficient as clearing up and draining the breeding places. The second method of breaking the cycle is to protect the individual from the bite of an infected mosquito, and under this head is included the protection of the patients already infected from the bites of mosquitoes. But patients suffering from malaria can not often be confined to the house. However, in malarial districts every house should be screened, as well as the beds, porches, etc. The third way of breaking the cycle is by the destruction of the parasite in the host by the use of quinin. For prophylactic purposes, the Italians use small doses frequently repeated, instead of large doses given less frequently. Wherever possible they have carried out a mixed prophylaxis, personal protection, as well as quinin prophylaxis; and they have succeeded in reducing the number of cases of malaria enormously.

DISCUSSION.

Dr. J. H. White, New Orleans: From my own knowledge I can testify to the truth of Dr. Thayer's statement that the real solution of malarial prophylaxis is drainage. Oiling is simply a makeshift, and never can be anything else, because it has to be done at intervals, like the giving of quinin, and will be forgotten. I have found that, in addition to screening the houses, it is necessary at regular intervals to fumigate those houses, because through carelelessness mosquitoes will get in when the doors are opened. This fumigation is not a serious task and should be repeated every seven days.

Dr. Victor H. Heiser, U. S. Public Health and Marine-Hospital Service. In sections of the Philippines people died at certain seasons of the year by the thousands. In these sections quinin in large quantities was distributed gratuitously by the government, and now it is rare for a death to occur there from malaria.

Dr. S. T. Rucker, Memphis, Tenn.: One important thing has been omitted, and that is the administration of calomel preceding the quinin. I am convinced that the mosquito is the chief infecting agent in malaria, but I doubt if it is the only one. I have seen malaria with chills and fever in February. I would like to ask Dr. Thayer how long the malarial plasmodium can live in a healthy individual without any physical manifestations.

Dr. William Krauss, Memphis, Tenn.: One of the difficulties of screening is that the screens in general use, No. 12 mesh, will allow the mosquitoes to pass through readily. We should teach the public that these insects are the carriers of the infection. It is probably not necessary to get rid of all the mosquitoes, for Colonel Gorgas has shown with reference to yellow fever that the disease dies out before all the mosquitoes disappear.

Dr. T. A. Casey, Birmingham, Ala.: I want to emphasize the fact that the mosquito is the sole carrier of the disease. I still find that many physicians in the south believe as Dr. Rucker just said, that the mosquito is not the only source of infection. When we consider its cycle of development, in the body of the mosquito and then in the human subject, and if one link in the chain is broken the disease will be prevented, I think the question is at once answered.

Dr. H. L. Sutherland, Rosedale, Miss.: An important matter is to screen the malaria patient until you get him thoroughly under the influence of quinin.

Dr. I. I. Lemann, New Orleans: In New Orleans it has been found that the *Anopheles* mosquito breeds in the swamps back of the city and along the walls of the river front where small quantities of water may collect. In this way it was found that the city was practically surrounded by the breeding places of this form of mosquito. On the other hand, the *Culex* and the *Stegomyia* breed only in the center of the inhabitable portion of the city. These conditions correspond exactly with our clinical experience.

Dr. J. A. Witherspoon, Nashville, Tenn.: Until a national bureau of health is established, with sufficient mony and sufficient men of scientific attainments, of course these great problems of prophylaxis must be carried on in a rather unsatisfactory way, but when that is established I feel that most of these infections can and will be controlled. The great danger of infection is from the patients who are walking around and can not be screened. But the trouble is that we stop giving quinin too soon. If the quinin be continued long enough, then we will get rid of the latent infections, and in consequence will have less malaria.

Dr. D. L. Wilkinson, Montevallo, Ala.: What we want and need more than anything else is education of the public, and physicians will be compelled to carry that on until a bureau of health is established to carry out these measures for us. And in that effort it strikes me that one of the best measures is that adopted a year or so ago by the Shelby County Medical Society. Four good lecturers were secured and public lectures were given on the prevention of malaria, typhoid and tuberculosis and on some other question of preventive medicine In some parts of the country streams are being reforested and I would like to ask how, in these new areas we can prevent reinfection

DR GEORGE DOCK New Orleans Late return of malarial fever has long been known I have seen patients coming up from Central America in the fall become ill in February, March and even in April in places where there was no malaria It has also been shown that spring malaria often comes out a couple of weeks after those mosquitoes that have been fairly quiet during the winter begin to move around I have frequently seen that in Michigan I would go farther than Dr Witherspoon and keep these patients on quinin all winter and in this way prevent a return

DR W S THAYER It is not known how long the parasite can live in the human host sometimes probably for years There are no accurate observations for a longer time than two years The question of reforesting streams will have to be determined very much with regard to the particular locality I would question whether it would tend to increase the malaria to any great extent I am not sure just how far a mosquito can be carried by the wind but probably not more than two or three hundred yards The length of treatment is an extremely important matter, and I can only second what Dr Dock has said Ross advises three months' treatment in every case of malaria It has been my habit to treat a patient fairly vigorously for two or three weeks, and then ask him to take two grains of quinin three times a day for from three to six weeks but I am inclined to think that he ought to take a large dose say six grains a day in divided doses for about three months after infection I do not think very large doses are necessary except in the malignant cases It has been shown that the accumulation of quinin is just as much after small doses as after very large ones It is important to remember that the quickest way of getting quinin into the blood is intravenously, next by the mouth and that the slowest way is hypodermically

(*To be continued*)

NEW YORK NEUROLOGICAL SOCIETY.

Regular Meeting, held Oct 6, 1908

The president, DR B SACHS, in the Chair

The Seat of Consciousness

DR FREDRICK PETERSON Psychologists, metaphysicians, physiologists and physicians have written a great deal concerning consciousness, but if they have said anything of any great significance it has eluded my observation The most tangible thing that I have been able to grasp in my reading is that consciousness is a stream, a flow a flight, a current, a thread an 'orderly succession of changes' I take it for granted that whatever consciousness may be it has a seat It has been assumed that if the body be removed portion by portion first the legs and the arms and then the trunk as far as the base of the skull that consciousness if the circulation and oxygenation be kept up, still persists in the head and that its seat is in the brain Such an experiment in effect, has often been performed for us in broken necks and other spinal cord lesions Those who have dared to surmise further have intimated that consciousness is diffused throughout the brain, or even that it is an attribute of the cortex of the brain alone In my opinion the seat of that power which produces the manifestations of consciousness is in the basal ganglia (probably the corpora striata) and consciousness is a peculiar summation of energy at that point capable of being directed like the rays of a searchlight into this or that portion of the brain The daily physiologic variation of consciousness in the condition of sleep is certainly a reduction in consciousness from the highest summation of energies to some lower level Sleeping and waking may be observed in a vast group of animals that have little or no cerebral development Furthermore the phenomena of sleep are observed in new born human infants despite the fact that the cerebrum is empty of experience and anatomically still much undeveloped as to its connections with the rest of the brain They are also observed in children born without a cerebrum and even in dogs deprived of the hemispheres In innumerable cases of extensive loss of cerebral substance, of a hemisphere, as in infantile cerebral palsies (a frontal lobe in the crow bar case, etc), consciousness itself seemed unimpaired throughout life These observations seemed to show that consciousness, at least as regards its variations in the condition of sleep does not reside in the cerebrum An other argument of a similar bearing is the fact that every individual with a brain stored full of all the experience of a lifetime is only actually awake at any one time around some particular small group of functions or ideas that occupy consciousness

Passing now to another series of pathologic conditions, the one disorder which has led me to think much of this subject is epilepsy in which disease loss of consciousness is the most extraordinary and often the only symptom for example *tic de salaam* and other forms of *petit mal*, in which the patient drops suddenly to the floor with loss of consciousness, and quite as suddenly rises again in full possession of his faculties The loss of consciousness is complete and often lasts but a fraction of a second How can we account for such a phenomenon? If consciousness were a diffused attribute of the whole brain what spasm of blood vessels or other physical process familiar to us could act and be readjusted with such speed? What portion of the brain is so constructed as to be, apparently in intimate connection with every other? The corpora striata There is no part of the brain of which we know so little As Edinger said, here we have 'a mighty portion of the brain that must be of enormous significance, otherwise it would not be always present, from the fish up to the man"

DISCUSSION

MR HENRY RUTGERS MARSHALL A few years ago it would have been a matter of surprise to find such a subject presented for discussion before a body of neurologists, as it would have been considered to belong more particularly to the field of psychology The thesis is open to discussion in that it attempts to describe consciousness in terms of energy We have become more or less accustomed to similar descriptions since the appearance of Ostwald s work in which he attempted to define consciousness in terms of energy, and since then psychologists and philosophers have been endeavoring to bring meaning into his statements, but without success The word consciousness as commonly employed has two diverse meanings For instance, when we refer to the consciousness of plants, of which Darwin has spoken we refer to psychic existence, as such When, on the other hand, we state that we had gone to the theater and met an old friend who so engrossed our attention that we were not conscious of the play, we used the word consciousness with an entirely different meaning We here referred to a state of "awareness" and that was entirely differenent from "psychic existence" as such When we speak of the seat of consciousness we may mean either the seat of psychic sense in man or the seat of awareness This latter is probably the form of consciousness to which Dr Peterson referred When we inquire as to the seat of consciousness as psychic existence, as such, we deal with a different question The evidence at our command at present favors a broad and exceedingly general seat of consciousness as thus considered In sudden loss of consciousness in an epileptic there is also a momentary paralysis—a sudden cessation of activities That distinction is important because it brings into relation with our states of clear consciousness all those states of what are commonly called our 'sub conscious' mental life those states which might better be called 'sub attentive consciousness'

Waking and sleeping, I believe, are objective signs or the same conditions which from another point of view were described respectively as clear consciousness and the lack of clear consciousness

PROF FREDERIC S LEE Does consciousness represent a special form of energy or not? I think that most physiologists would hardly agree that consciousness represents energy It seems to me that the best working hypothesis for the physiologist is that consciousness is something of unknown nature which accompanies the activity of certain brain structures I do not like the term "epiphenomenon" to express that idea, but since that is the common and accepted term I would use it. Consciousness, then, is an epiphenomenon accompanying the activity of certain brain structures; or, rather, it is one of the modes of manifestation of their activity, just as chemical, thermal and electrical phenomena were other modes. Consciousness could not put into activity the brain structures. I would not necessarily confine consciousness to the activity of the cerebral cortex only, although I am inclined to believe that it is particularly associated with the working of cortical cells. Bechterew claims that in early life certain parts of the brain below the cortex act consciously, and that as the tracts between these and the cortex become myelinized and functional, conscious activity comes to be pre-eminently associated with cortical activity. On the theory that the *corpus striatum* works through the mediation of the cortex, how would Dr. Peterson interpret the behavior of one of Goltz's dogs, from which the cortex had been entirely removed?

Dr. Adolf Meyer: Dr. Peterson's thesis brings back to us the proposition which Dr. P. Carus advanced about thirteen years ago in the *Journal of Comparative Neurology*, based largely on the argument that the corpora striata formed a large, bulky part of the brain to which no other function could be assigned. Gaule in turn assigned the function to the optic thalamus. Ignoring entirely the question of what we meant by "consciousness" as a positive function, it seems that the evidence that Dr. Peterson has presented could best be summed up as evidence of vulnerability of mechanisms of consciousness by a lesion in the basal region. It is evidence in favor of the possibility of localizing the lesions in some types of unconsciousness. As soon as we try to make positive inferences, *i. e.*, as to the "seat of consciousness," we are bound to meet a number of difficulties, and one of them is this: contrary to Dr. Peterson's assumption, the corpora striata has relatively very obscure connection with the rest of the brain. This is one of the greatest stumbling blocks to the theory advanced that the corpora striata should be of such fundamental importance. So far as we know, its connections with the cortex are extremely scanty, and with the rest of the base its connections are essentially those with the hypothalamus. On anatomic grounds alone it would be difficult to explain any connection with the corpora striata and the "seat of consciousness," leaving out of consideration the question whether or not the "seat of consciousness" could be a safe problem to-day.

Dr. Smith Ely Jelliffe: In very general terms, consciousness might be regarded as the in-streaming of all the sensory functions, and with the cutting off of the sensory or perceptive functions, a loss of consciousness follows. To illustrate that point we need not consider the effect of an anesthetic, because in alcohol we have an agent, *par excellence*, which cuts off, one by one, the different sensory perceptive functions, little by little, until we have a non-conscious residua. So far as the seat of consciousness is concerned, the corpora striata simply acts in the capacity of a cut off by reason of the anatomic distribution of the fibers in that region. Instead of being the seat of consciousness, I look on it as a gateway through which the fibers pass, and any injury in that area would be apt, therefore, to have a widespread effect.

THE SERUM DIAGNOSIS OF SYPHILIS IN ITS RELATION TO NERVOUS DISEASE

The Development and Character of the Wassermann Test.

Dr. C. F. Bolduan: The Wassermann reaction, briefly outlined, is as follows:

Two tubes are prepared with the following contents.

Tube 1.—Extract of the liver and spleen of a syphilitic fetus, representing the syphilitic organism (or antigen), plus serum to be tested.

Tube 2.—Red blood cells of sheep or other animal, suspended in normal saline solution, plus serum of a rabbit which has been immunized to the particular red blood cells used.

Complement (a substance necessary to all immune reactions, which existed in the fresh serum of all animals) in the shape of fresh normal guinea-pig serum, is added to Tube 1 and allowed to stand. At the end of half an hour the content of Tube 1 is added to that of Tube 2. If the serum in Tube 1 came from a syphilitic individual, its relation to the extract of antigen is a specific one, and complement will be absorbed thereby; so that, when the contents of Tubes 1 and 2 are joined, no hemolysis of the red blood cells in Tube 2 will take place. If the serum is not from a syphilitic, complement will not be absorbed, but will remain active to cause hemolysis in Tube 2. Hemolysis is observed in the test tube as a tingeing of the whole field with a transparent red color. The red corpuscles have been disintegrated and the hemoglobin liberated. In the absence of hemolysis the solution of red cells remains turbulent and opaque. The test, of course, involves numerous controls and a careful standardizing of the hemolytic serum and of the syphilitic extract.

Technic of the Wassermann Reaction: Its Practical Application with Reference to Diagnosis, Prognosis and Treatment of Nervous Disease.

Dr. E. Castelli:

1. From the social standpoint, the serum diagnosis of syphilis represents one of the greatest achievements attained by medicine at the present time. The rôle played by syphilis in the life of mankind requires no explanation. The highest coefficiency to degeneracy and insanity is created by syphilis.

2. If we were now in a position to tell our patient that notwithstanding his previous syphilitic infection he could marry and create a healthful progeny we would certainly have at our command a tremendous factor for benefiting a large proportion of our fellow beings.

3. If we could establish the fact that syphilis is curable, and did not hang like the sword of Damocles over a man's physical and mental future, again medicine would triumph.

4. From a legal standpoint, the fact that we might be able to aid either the prosecution or the defense with the knowledge that the criminal had a claim on the court's leniency by reason of a previous syphilitic infection, which had produced a derangement of his mental poise, might become an important factor in the administration of justice.

5. The serodiagnosis of syphilis would be a means of differential diagnosis during the pre-paralytic stage, when the general symptoms were indefinite and generally masked by a well defined neurasthenic syndrome. The differential diagnosis between general paralysis and neurasthenia during this period would represent the real prophylactic warning. The patient, during this pre-paralytic stage, is dangerous to himself, his family and to society at large, and our early recognition of the condition makes possible the safeguarding of the patient.

6. While the serodiagnosis of syphilis in its present condition is not perfect, and owing to its complicated technic and to the difficulty of procuring the necessary ingredients it is limited to a few privileged students, yet it has the indisputable advantage of furnishing us with a rich amount of positive diagnostic data, and I consider its adoption in the various hospitals and medical institutions not optional, but absolutely necessary.

Demonstration of Wassermann Reaction Test.

Dr. Noguchi, Rockefeller Institute: After demonstrating the Wassermann reaction, Dr. Noguchi showed briefly a reaction evolved by him during some experimentation with the various albumin reactions in the spinal fluids of general paralysis and other disorders. This was obtained as follows: 1 c.c. of the spinal fluid to be tested is placed in a test-tube whose diameter is 1 cm. or less. To this is added 5 c.c. of a 10 per cent. solution of butyric acid. The tube is then heated until the fluid is bubbling, and while still hot 1 c.c. of a normal (4 per cent.) solution of sodium hydrate is added. In nearly all spinal fluids and opalescence or cloud occurs, but in the spinal fluid of general paralysis the cloud soon separates into a definite flocculence which is characteristic. The flocculence usually appears in a few moments—rarely requiring more than twenty minutes. The reaction has the advantage of being positive in a quantity of 1 c.c. or less, and of being a qualitative as well as a quantitative test. What the flocculence may mean is not known, but it may consist of some globulin fraction which is found only in syphilitic or meta-syphilitic disorders of the nervous system. That the reaction is not entirely quantitative is shown by the fact that many fluids from nonparalytic patients give much richer clouds than those from paresis patients but the clouds do not flocculate

Discussion on Serum Diagnosis of Syphilis at Ward's Island

Dr J W Moore State Pathological Institute Ward's Island So far 80 cases have been tested at Ward's Island by the Noguchi method 50 undoubted cases of paresis gave 48 positive results The 2 negative cases did not seem peculiar in any way Of 3 cases of cerebral syphilis 2 gave positive reactions Of the nonparalytic cases tested 5 were alcoholic psychoses 2 manic depressive cases 1 paranoic state, 1 imbecile and 1 case which was diagnosed as Korsakow's delirium but which proved at autopsy to be due to a fractured skull with extensive diffuse dural hematoma Only 1 of the non paralytic cases gave a positive reaction This was a case, diagnosed as dementia præcox, with however increased knee jerks and speech defect In 5 doubtful cases there were 2 positive results and 3 negative In the majority of cases of paresis the Wassermann reaction was also carried out Four cases of general paralysis which were negative to the Wassermann test were positive to the other Four gave the Wassermann reaction much less definitely than did the Noguchi reaction In no case was the Wassermann test the more conclusive of the two In two of the cerebral syphilis cases in which it was tried it gave a negative result

Dr B Onuf Dr Castelli states that in a large percentage of cases of general paresis—70 or 80—the Wassermann reaction was positive, and also in about 60 per cent of cases of senile dementia Can we conclude from that that senile dementia is simply a late form of general paresis? Does syphilis produce a rather rapid exhaustion of the nervous system while in senile dementia identical changes occurred in a longer course of time? Does Dr Castelli mean to identify senile dementia with general paresis?

Dr Boleslaw Lapowski On account of the technic of the Wassermann reaction and the material and control experiments that it involves it will always remain a laboratory test By terming it the "Wassermann reaction' we are inadvertently doing an injury to others who laid the basis of the reaction Wassermann simply substituted dissolved substances of bacterial extracts of organs instead of emulsions of bacteria, but the basis was the fact discovered by Bordet and Gengou, and to them at least some credit is due The test is of undoubted value in corroborating or establishing the diagnosis of latent syphilis but even then it can not always be relied on, and in dealing with primary or secondary syphilis it is not necessary

Dr B Sachs While the Wassermann test can not be made at the bedside, its technic is not difficult and can easily be acquired For the present, of course, this test, like many others, will be restricted to the laboratory and has to be made by persons specially qualified along those lines So far, the reaction has been practically limited to cases of suspected tabes or general paresis, but at the Mt Sinai Hospital an effort is being made to employ it in other doubtful spinal or cerebral cases in which syphilis is suspected

INTERNATIONAL CONGRESS ON TUBERCULOSIS.

Held at Washington D C, Sept 28 to Oct 3, 1908

(Concluded from page 1813)

SECTION II—CLINICAL STUDY AND THERAPY OF TUBERCULOSIS (Concluded)

Hygiene of the Mouth, Nares, Pharynx, Intestines, Skin, Mucous Membranes, Lymphbodies, Lungs; Prevention of Colds

Dr Noble P Barnes, Washington D C Hygiene of the mucous membrane is essential to the cure and prevention of disease Only by free drainage and free air space in the nasal cavity can we hope for relief and cure of ear disturbances recovery of diseased pulmonary and gastrointestinal mucosa or arrest and non recurrence of a tuberculous process In practicing lung gymnastics never expand the chest beyond the degree of comfort for fear of tearing open old wounds or rupturing air cells and expel the air through the nose instead of the mouth or puckered lips as practiced by most teachers of physical culture The turbinates are cooled by inhalation, warmed by exhalation and dust caught on the nasal hair and mucous membrane will be blown out instead of drawn further in The digestive tract as a route for tuberculous invasion is of first importance in infants and young children The pasteurized milk and other sterile foods are "love's labor lost" unless the many other methods of infection are recognized and eliminated Pacifiers are disease carrying articles that deform the mouth produce adenoids, and create the sucking habit that is still observed in gum chewing, nail nibbling adults The expressions "catching cold," "cold in the head, chest and back" mean nothing to the trained mind If the mucous membranes are free open, well drained and healthy, there will be no army of organisms waiting for a lowering of resistance by exposure to atmospheric changes or fatigue or hunger to operate in the production of a rhinitis bronchitis, tonsillitis or rheumatism To prevent 'colds," observe the proper hygiene of the skin and mucous membrane, avoid fatigue long hunger dust bad air, mufflers and chest protectors No exercise in the play park can overcome the injury from studying in foul air in school rooms or sleeping in closed apartments nor can fresh air and good food overcome disease caused by defect The new hygiene should be taught in the schools not that about the effects of tobacco and alcohol, but that the avenues to infection are through the skin and mucous membranes and that these structures must be kept clean and healthy

Isolation of Poor Consumptives in General Hospitals

Dr M Letulle Paris Patients with "open tuberculosis," admitted to hospitals for general diseases, must be isolated "Measures of collective preservation" must be carried out in such a manner as not to injure the poor consumptives who entrust their health to our keeping The treatment of tuberculous patients in a hospital must be not only "hygienic and dietetic" and as completely so as in a sanitarium, but also moral It is, therefore, absolutely necessary in curable cases to secure to the consumptive the joy of living and the hope of recovery Consumptives admitted to general hospitals must be divided into three distinct administrative classes, without daily communication, so as to secure complete isolation (1) Early cases (without expectoration), (2) open cases, considered curable, and suitable for sanitarium treatment, (3) "chronic consumptives," who merely require humane care and treatment This division into three classes must be made as early as possible With that end in view, every patient suspected of pulmonary tuberculosis must be isolated in a separate room immediately after his admission, until the medical diagnosis has been definitely made

Rest of the Lung in Pulmonary Tuberculosis

Dr Norman Bridge Los Angeles, Calif The tuberculous lung should be kept as still as possible especially if the disease is unilateral There are numerous arguments in favor of this view it is the nearly universal opinion in tuberculosis of other organs to keep the part as still as possible and I can discover no reason for making an exception of the tuberculous lung Immobilization relieves symptoms and helps toward recovery Violence to a wound retards healing and increases scar tissue Analogous things happen to the tuberculous lung Violent coughing and lung gymnastics may disseminate the disease in the lung Stretching the diseased tissue is liable to injure it The Bier method of passive congestion doubtless tends to retard numerous diseases and helps toward recovery It is more effective in a lung that is kept still Artificial immobilization in unilateral cases always seems to help the lung toward recovery so does pleural effusion of serum Cough to expel phlegm from the air passages is not important but much cough is harmful Pus in the windpipe or bronchial tubes is absorbed into the system very little and does little if any harm Hence to suppress cough by will power or even mild drugs is useful The right view of this subject must be reached by analogy and good sense for statistical records are hard to make The difficulty lies in the great number and va riety of the natural and spontaneous movements of the lungs, which vary widely in different patients. It would require at least 1,200 patients, under observation for a year each, by an accurate and judicially minded observer, before any sharp generalization could be made. No such test has been made or is likely to be. Analogy and a due sense of proportion requires that a tuberculous lung should be kept as still as possible.

Ten Years' Experience in Sanatorium Work.

Professor Gotthold Pannwitz, Berlin, discussed (1) his experience with regard to the construction and arrangement of sanatoriums; (2) his administrative experience; (3) the results of treatment; (4) the supplementary measures before and during sanatorium treatment; and, finally, (5) his special experience in children's sanatoriums:

An important lesson, which has been learned by experience, is that the rest-cure in a sanatorium must be followed by a period during which the convalescent engages in some light agricultural occupation (occupation-cure), so that he may again become accustomed to regular manual work and thus render the results of treatment more permanent. The medical treatment, besides the general hygienic and dietetic measures, should include the use of tuberculin, administered with strict regard to the individual and with the greatest caution, so as to avoid producing any reaction. The results of the tuberculin treatment are becoming more and more satisfactory. The most important adjuncts to the free sanatorium are the convalescent camps or homes, a general supervision of living conditions by social workers from the supporting dispensaries, the rendering of assistance to patients' families, and finding work for convalescents.

In children's sanatoriums special stress should be laid on the educational feature. These institutions should be arranged on the simplest hygienic plan, in order to avoid getting the children accustomed to comforts which, for want of means, can not be supplied in their own homes. Light and air, plenty of soap and water, but in the simplest imaginable form, are supplied, and the children are constantly taught the simplest rules of hygienic living—how to sleep, breathe, chew, harden the body, keep clean, and take exercise. A sanatorium for children must have some farming facilities, so that, after the rest-cure of several weeks, the child may continue to live in the open air for some time and engage in gardening or other outdoor occupation, and thus render the results of treatment more permanent.

Cost and Maintenance of Sanatoria, with Special Regard to Institutions Operated by Life Insurance Associations.

Dr. Richard Freund, Berlin: Tuberculosis sanatoria must be developed into special hospitals for tuberculous patients. They must be massively built and must be adapted for use during the whole year. The interior arrangement must be planned to allow the maintenance of perfect cleanliness. In building these sanatoria only the best materials are to be used and equipment should be installed with greatest care. Such a plan of construction will save expensive repairing and renovating and make certain the permanence of the institution. The most expensive is the cheapest. The rooms should be furnished in the simplest manner, every luxury is to be avoided, yet care should be taken that the sanatorium presents an air of comfort and is inviting. In order to secure the best quality of food with the lowest possible average cost per inmate, each sanatorium should have its own farm near by, which supplies the sanatorium, and on which also tuberculous patients might find occupation.

Graduated Labor in Pulmonary Tuberculosis.

Dr. M. S. Paterson, England: The idea that work is to be employed in every case and at all times is erroneous. The system of graduated labor at Frimley Sanatorium begins with almost more extreme rest than in any other sanatorium. In conjunction with Dr. Inman I have shown by the opsonic index that exercise has a definite effect on the blood in pulmonary tuberculosis. It also influences the temperature. Influence on blood and temperature I believe to be due to toxins produced at the site of lesion or autoinoculation (Wright), when the toxin reaches the blood and lymph stream. Persistence of this fever and the state of the blood leads to the death of patient; absolute rest is necessary to prevent this. Patients with temperature even of 99 F. by mouth and with headache are sent to bed; they are not allowed to wash themselves or to go to the lavatory. Every possible means is used to stop cough not productive of sputa. Graduated exercises are begun later and careful watch kept on temperature. The patients' work is gradually increased under constant supervision until such time as they can perform the heaviest work without rise of temperature. Chief indications of autoinoculation are: 1, Loss of appetite (usually meaning too hard work); 2, a patient is seen to do his work as if it were an effort; 3, an irregular swinging temperature always below normal; 4, a temperature of 99 F. in early cases in men; 5, a temperature of 99 F. and headache.

Treatment of Tuberculosis in the Patient's Home or in Other Places than Sanatoria.

Dr. Charles L. Minor, Asheville, N. C.: The hygienic and dietetic treatment is now universally recognized as a fundamental part of any and all rational treatment of pulmonary tuberculosis. This method has usually been most carefully applied in closed sanatoria, and it has been supposed that it could only be satisfactorily carried out in such institutions. But, granted sufficient care and pains, this sanatorium treatment, as it is often called, can be as well applied outside such places. The essential features of this method as to their adaptability outside of sanatoria are: 1, Careful personal medical oversight, strict discipline and close supervision; 2, thorough instruction; 3, systematic and hygienic arrangement of the patient's life; 4, effect of the example of other patients and of the *esprit de corps;* 5, nursing; 6, proper housing location and feeding; 7, suitable climatic conditions. All are obtainable unless the patient is handled alone in his own home, when the features mentioned under 4 are missing, or unless he is so poor that those under 7 can not be had. The handling of the very poor, ignorant and criminal is a sociological question, more than a medical one. Handling a chronic disease like pulmonary tuberculosis calls for different methods than those applicable to the ordinary acute disease. The former call for much more detailed work and closer personal relations, and unfortunately chronic cases are often by the profession regarded as uninteresting and tedious and unfruitful of results, a very erroneous view.

Treatment of Tuberculous Patients in Their Homes and Places Other Than Sanatoria.

Dr. Thomas D. Coleman, Augusta, Ga.: This is a question of the greatest importance to the individual, the family and society because the greater number of tuberculous patients must be treated in their homes, because of personal choice, individual necessity and the scarcity of suitable sanatoria, in comparison with the number of tuberculous sufferers. It is not to be confounded with the climatic treatment or an entire change of climate in the affected, whether the treatment be carried out in a sanatorium or suitable private home or boarding place. As rigid discipline and as intelligent medical oversight may be carried out in the home as in the sanatorium. The location of the home must be considered, with reference to altitude, soil, sunshine and shade, shelter from winds, location and general equipment of the room with reference to the home and surroundings, hygienic and dietetic routine, specific treatment, and the treatment of the symptoms.

Diagnostic Value of the Cytologic Examination of Tuberculous Effusions in the Various Serous Cavities.

Dr. A. Cade; Lyons, France: The cytology of effusions (Widal) requires a simple and easy method of examination and is of considerable aid in determining the nature of a pleurisy. A great predominance of lymphocytes is a strong argument in favor of tuberculosis. There is no danger of making a mistaken diagnosis of tuberculosis on the strength of the cytologic findings in a pleural effusion; the only risk is that the condition may be mistaken for something else, as abnormal formulas are by no means exceptional. The anomalies of the cytologic formula are susceptible of various explanations, but some of these anomalies are still mysterious. The cytology of tuberculous effusions in other serous cavities has a questionable semeiologic value. We must except the great predominance of lymphocytes in tuberculous ascites, an occurrence which, however, is by no means common. In general, cytologic findings must be interpreted with caution; they often need to be controled by other laboratory examinations and should always be compared with the data obtained by clinical observation. The foregoing conclusions are the result of numerous observations made during the past seven years in the laboratory of my clinic, most of them with the collaboration of Dr. Barjon.

Tuberculous Rheumatism and Inflammatory Tuberculosis

Professor Antonin Poncet, Lyons, France: My researches during the past ten years have established the existence of articular and non-articular tuberculous rheumatism. This last comer among the infectious rheumatisms should be placed in the front rank, as it is the most common, and its frequency is explained by the prevalence of tuberculosis. The various forms of tuberculous rheumatism range from the acute forms (acute and subacute articular rheumatism) through all the intermediary grades to the chronic forms (nodular deforming ankylosing articular rheumatism). As a rule the articular lesions do not exhibit the characteristics of classic tuberculosis, such as tubercles, caseous infiltration, etc. (macroscopic features), or tuberculous follicles, giant cells, etc. (microscopic features) that constitute the characteristic picture to which the term specific tuberculosis may properly be applied. The lesions, on the contrary, are made up solely of inflammatory tissue; hence, the name "inflammatory tuberculosis," which I have given to this variety of tuberculosis. There are accordingly two great varieties of tuberculosis: specific tuberculosis, which has been admirably studied and is well known, and inflammatory tuberculosis, with an insignificant anatomic reaction, purely inflammatory, as in all infections and intoxications. It is this latter form of tuberculosis that I have studied more particularly during the past five years with Dr. René Leriche. It embraces the attenuated forms of tuberculosis which until that time had not been properly recognized. Its range is no less extensive than that of virulent specific tuberculosis. It attacks all the tissues, all the systems, all the organs, as well as the joints, where its existence was first revealed to us under the form of tuberculous rheumatism. Often it takes the place of the arthritic, fibrous or neuro-arthritic diathesis, etc., terms which are becoming more and more vague and less acceptable because they merely refer to syndromes brought about by the tuberculous virus under a great variety of circumstances.

Tuberculosis in Hospitals for the Insane

Dr. Richard H. Hutchings, Ogdensburg, N. Y.: Reports from New York state show that the death rate of the insane in custody is 16.6 per cent., as compared with 10 per cent. among the general population from tuberculosis. In Massachusetts more than 14 per cent. of the deaths among the insane are attributed to this disease; the Government Hospital for the Insane reports more than 20 per cent. of tuberculous lesions found postmortem; in the St. Lawrence State Hospital active tuberculous lesions have been found postmortem in 14 per cent. of the cases. The frequency of the disease among asylum inmates differs in different parts of the country, being more frequent, in general terms, in the east and least frequent in the newer states of the west; it depends to some extent on (1) the environment of the patient admitted, from crowded cities or rural districts; (2) the conditions existing in the hospital itself, as overcrowding, poor ventilation, and the general standard of care maintained. The frequency of tuberculosis among the different classes of the insane—most frequent among the idle and inactive and those with indoor employment, and least frequent among the patients regularly employed at work in the open air—is supported by an examination of the death rate from this disease in the two sexes. In our asylums the women as a rule are employed at domestic and indoor work, while all the garden, farm and outdoor work is performed by men. In New York state during the past eighteen years there have been among the insane in custody 28,106 deaths from all causes; of these 15,242 were men and 12,864 were women. Among the men 1,463, or 9.5 per cent., died of tuberculosis, while among the women there were 2,596, or more than 20 per cent., died from this disease. The number of insane in whom an actual diagnosis of tuberculosis has been made ranges in various American asylums from 0 to 14 per cent., the average being about 3 per cent. These figures are probably below the truth because of the difficulty in making physical examinations. Where measures are employed to isolate the tuberculous patients there has resulted a diminution in the frequency of the disease. Measures for the prevention of tuberculosis include, besides the ordinary measures for cleanliness, a more critical examination of new patients, employing tuberculin when necessary, with isolation of all infected persons, reduction of overcrowding in wards and dormitories, free ventilation from open doors and windows, daily exercise and employment out of doors for both men and women, and sterilizing of all garments and bedding before such are used by a second person.

Rôle of Pleural Adhesions in Sudden Death, Asphyxia, Severe Injuries

Drs. Lacassagne and E. Martin, Lyons, France: Pleural adhesions occur in 80 per cent. of cases. They are most frequently of tuberculous origin. Every individual with pleural adhesions is liable to sudden death. Every patient with adhesions falling in water is a doomed man (Lacassagne). Adhesions may aid rapid death in anesthesia or after severe surgical injuries. Their importance is therefore great in general medicine and in legal medicine. They are the more injurious as they are more extensive.

Value of Roentgen Ray Examination in Early Diagnosis of Pulmonary Tuberculosis

Dr. Paul Krause, Jena: Infiltration at the apices sufficiently extensive to be demonstrated by percussion produces a more or less deep shadow. The *x*-ray examination is superior to physical diagnosis, inasmuch as it shows that in many cases the process is more extensive than was at first supposed. Infiltrations that can not be demonstrated by percussion can often be demonstrated by means of an *x*-ray photograph. Simple catarrhal processes in the early stage can not be demonstrated either by the fluoroscope or by taking an *x*-ray photograph. Later, the apices, owing to the diminished amount of air, appear dark and do not clear up during inspiration. If the case is very important for practical reasons, an *x*-ray photograph should always be made. The level of the apices, which in doubtful cases may be determined by orthodiagraphic measures, is of no importance unless the difference exceeds from 1 to 1.5 cm. The width of the apices has not been sufficiently studied with the *x*-ray to be considered a diagnostic point of any value. Ossification of the first rib is readily demonstrated by means of the *x*-ray, and, after Freund, may be utilized as a sign of early tuberculosis. The normal clearing up of the apices during respiration is often absent on one or both sides in early tuberculosis. Lagging of the diaphragm on the diseased side (Williams' phenomenon) has no diagnostic value. The position of the shadow of the ribs in the *x*-ray picture can only be utilized with great caution, if at all. Changes in the apices are usually not found, but alterations of the shadow at the hilus, indicating the presence of indurated caseous or calcified bronchial glands, or infiltrative processes in the neighborhood of the hilus of the bronchi, is, on the other hand, most important. I have frequently seen the picture of a central pneumonia due to a mixed infection with pneumococci progressing slowly in spite of the disappearance of the fever, and after weeks being recognized as a tuberculous process by percussion and auscultation and bacteriologic examination. The *x*-ray examination should be regarded as coordinate to physical examination, but it has its limitations. It tells us nothing in regard to the etiology of the process. The *x*-ray examination frequently reveals the infiltrative process with a perfection which closely approximates that of the autopsy table. Cavities of every size from that of a pea upward, whether superficial or deep-seated, as well as calcified foci, reveal themselves in the *x*-ray photograph. Sources of error arise from the fact that shadows at different depths in the lungs overlie one another. In many cases infiltrative processes of a non-tuberculous origin (tumors of the lung, bronchiectasis, pulmonary abscess, pulmonary gangrene) can be differentiated. In the main, however, the *x*-ray diagnosis *merely confirms or completes the clinical findings*, and is limited to the detection of differences in density in the lung.

Recognition of Pure Pneumothorax, without Exudate, in Pulmonary Tuberculosis.

Dr. Hermon von Schrotter, Vienna, with the aid of tables and radiograms, discussed *pneumothorax occurring without exudate in the initial stages of tuberculosis*:

In individuals who were formerly apparently well and without any special accident, air enters the pleural cavity. In spite of marked displacement of the mediastinum, the symptoms may be relatively trivial. Similarly, the objective symptoms may be so indistinct or so uncharacteristic that it would be impossible to make a certain diagnosis without the aid of *a radioscope or the spirometer. The etiologic* connection of the pneumothorax with tuberculosis *can only be determined* by other investigations or by a careful and prolonged study of the later course of the case. The fact that pleural adhesions are absent and that the air enters into a normal pleural cavity affords the opportunity to study the phenomena of mediastinal displacement, the mechanism of respiration, and the vicarious *labor of the unaffected lung, in what might be called* its "pure orm." *It is also possible to follow out by observation or* suring interesting phenomena which as yet have not been ·iently appreciated. Thus, on the lung whose maximal action is toward the hilum, the phenomena of pulsation an be demonstrated. One can also study the change in the size of the lung during respiration, the lung capacity and the respiratory gaseous interchange as well as if the one lung had been artificially removed. By means of the radioscope, controlled by the *simultaneous employment* of the spirometer, *one can* study the course and rapidity of the spontaneous disappearance of the pneumothorax, or, what amounts to the same, the re-expansion of the lung. A deficiency in the vital capacity of a patient amounting to from 1,000 to 1,500 c.c., particularly in an individual already studied, of itself permits a diagnosis of (recent) entrance of air into the pleural cavity, even though the remaining physical signs are doubtful. It is of further interest that the above-described condition may recur two or three times in individuals with small, circumscribed apical affections, while only slight variations occur in the manifestations and absorption of the pneumothorax. I have seen four such cases and have been able to study two of them along the lines just laid down. One of these patients still lives and comes at regular intervals for examination. He now shows (one year after the last recurrence of his pneumothorax) definite symptoms of an affection of the left upper lobe which had formerly been completed free. The other patient died after two attacks of pneumothorax. The course of the disease extended over several years and toward the end was rapid, although aft[illegible] the healing of his first attack of pneumothorax definite s[illegible] *of specific disease of the lung* could not be [illegible] Another man of 23 years may be

sion was *distinctly increased*. Several times the per-minute volume was *found to average* 10.5 L., with the respiratory rate at 22 a minute.

Specific Aids in the Diagnosis and Prognosis of Tuberculosis.

Dr. Silvio von Ruck, Asheville, N. C.: Of 300 patients at the Winyah Sanitarium whose sputa were negative, subcutaneous diagnostic injections of tuberculin gave positive results in 75 per cent. Of 26 healthy persons none reacted to instillations of 1, 2 and 4 per cent. solutions of alcoholic precipitate of old tuberculin into the same eye. In 23 cured or arrested cases none of the patients reacted. Of 18 tuberculous patients treated with specific remedies six months or longer 31.8 per cent. reacted. Of 34 under specific treatment less than six months 47.06 per cent. reacted. Of 44 not yet treated specifically 65.9 per cent. reacted. The influence of specific medication on the power to react to tuberculin is manifest. Of 67 tuberculous patients tested by v. Pirquet's method with 50 per cent. solution of human tuberculin 44 were positive, 19 negative, 4 doubtful. Of 16 cured patients 12 were positive, 3 negative, 1 doubtful. All these patients had not reacted conjunctivally. Of 24 clinically non-tuberculous 12 were positive, 1 gave a late reaction, 11 were negative. The use *of bovine tuberculin, both in the conjunctival and cutaneous* tests, side by side with the human, has not yielded results from which any definite conclusions can as yet be drawn. The tuberculin reactions as well as the serum reactions are specific and of definite value in cases in which the diagnosis of tuberculosis is not decisive by other methods. A continuous *increase in the agglutinating power* is favorable prognostically, *but I have not found any prognostic conclusions* possible from the tuberculin reactions.

Coagulability of the Blood in Pulmonary Tuberculosis: A Preliminary Investigation.

Dr. Myer Solis-Cohen, Philadelphia: A study of the coagulability of the *blood in tuberculosis* has been strangely neglected, Vierordt in 1878 and I myself in 1907 being the only ones to have reported such investigations. Yet the importance of this subject should be evident in view of the frequent occurrence of hemorrhage in this disease and the almost universal use of calcium chlorid for such a complication. Wright's *assertion that hemorrhage in typhoid is associated* with defective coagulability lends an added interest. One hundred cases of pulmonary tuberculosis were examined, 540 observations being made. The blood was tested according to the method which I have advised. Drops of blood were deposited on the inverted lid of a German stender dish and covered by the dish, which was held *in place by a rubber band*, the inverted dish being then placed in a pan of water kept at a temperature of 37 C. (98 F.). At intervals the dish was removed *and tilted*, the drops *sagging and* becoming tear or pear-shaped on profile view and denser below and clearer above on full view before *clotting* occurred. When coagulation was complete the drops did *not move* when seen from the side *and when looked* at in front were denser in the center or showed an even density. The average clotting time of all the cases was 5 1/6 minutes, being practically the same in the different stages of the disease. The examinations showed that persons with increased coagulability *are probably* less liable and those with deficient coagulability probably more liable to

SECTION V—TUBERCULOSIS IN CHILDREN—ETIOLOGY PREVENTION AND CURE

Comprehensive Program for Prevention of Tuberculosis: Relative Functions of Available Agencies

DR LIVINGSTON FARRAND New York The prevention of disease is to be attained (a) by eliminating centers of infection and (b) by raising the resisting powers of individuals Elimination of centers of infection depends on adequate facilities for early diagnosis for treatment of curable patients, for the proper care of advanced patients and on such restrictive sanitary regulations as may be found necessary Increasing the resisting powers of the population depends naturally on a higher standard of living with a wider observance of a sound hygiene, which in turn can only be brought about by an extensive campaign of education The available agencies for attaining these ends may be classified as (1) official, and (2) private The official agencies are the fundamental ones In the United States these are national state and local The possible rôle of the national government in the campaign is somewhat vague and difficult to define The value of a national department or bureau of health in the tuberculosis field would probably be chiefly educational and coordinating The state government is similarly of minor importance, although prominent historically The state sanatorium is relatively unimportant, and all state foundations have certain disadvantages The state health authorities, on the other hand have a definite function in the educational campaign, and state legislation is required for certain purposes Local official authority is the chief factor to be considered Our present aim should be to arouse a sense of responsibility there Private agencies are chiefly (a) organizations for the prevention of the disease, and (b) institutions for its treatment Private agencies are necessary in arousing public sentiment and official responsibility Their objects should be to carry on a campaign of popular education until public authorities assume the task when they should turn their energies into other fields It may be necessary to establish dispensaries, sanatoria, and hospitals under private foundations, but only as expedients and not as final means Dispensaries and hospitals are of superior importance as contrasted with sanatoria Hospitals for patients in advanced stages are the great present need in the United States Educational association and effort is of prime importance at the present time

Influence of Overwork and Nervous Strain in Tuberculosis.

DR GEORGE DOCK Ann Arbor, Mich, discussed the general nature of tuberculosis its effects on the body and the possible modifying influences of overwork and nervous strain on those processes

To keep the tuberculous patient at the highest point of efficiency, and with the least danger to others causing further illness and expense in an ever widening circle he must be cared for when sick or when overwork is inevitable This requires a great increase of hospital facilities for the tuberculous As part of the prevention of overwork and nervous strain it is just as essential that the family of the patient is so well cared for that he will take advantage of facilities for treatment and remain under treatment until his efficiency is raised to the highest possible point Also when well enough to work, he must be supplied with proper facilities for the nearest approach to a living wage

Cost of a City's Ransom.

HON TALCOTT WILLIAMS Philadelphia gave an estimate of the expenditure which would be required to control tuberculosis in Philadelphia

The ultimate extirpation and disappearance of tuberculosis exactly as leprosy has disappeared in the past is the final goal to which this congress tends Encouragement exists in the decrease of the relative death rate from consumption but while in Philadelphia, the deaths from this cause per 1 000 living have in 20 years fallen off relatively one half the absolute aggregate of those dying has remained at about 3 000 for 20 years up to 1906 The reduction in death rate in 1907 may or may not prove permanent Statistics of these 20 years show that while in the general community tuberculosis is on the decrease, the growth of poverty, want and wasting diseases tend to maintain the ratio of deaths from general causes While the means of infection remain, the frequency of deaths from this disease will continue to occur particularly among the less favored classes of society The infection itself must be removed A city should be held responsible as much for suppressing preventable disease as for keeping its roads in repair Its citizens owe as great a duty to the preservation of health as of order Philadelphia to day has about 3,000 deaths a year from tuberculosis, although the rate was lower in 1907 In the opinion of the local bureau of health, judging from current reports of cases, of the 10 000 consumptive persons in Philadelphia 3 000 may be expected to succumb within twelve months, and another 1,000 four months later, making at the present moment 4,000 tuberculous patients in that city alone needing expert care The ransom of a city, therefore, calls for hospital or sanitarium provision for 4,000 in the last stages of the disease, and watchful care over 6,000 more to insure their proper nourishment and to prevent infection of others The hospitals of Philadelphia have 1,500 bed capacity unused Hospital provision for 2,500 more would cost in these days of concrete building materials not over $1 250,000 The maintenance of 4,000 consumptives destined to succumb within two years, and a peril to all about them, would cost at the average hospital rate of a dollar a day, $1,460,000 annually The care food and supervision of the remaining 6,000 not yet helpless would cost $600 000 a year This sum would insure to them medical attendance, services of visiting nurse and proper food Therefore by the yearly expenditure of $2 000,000, in addition to the initial sum of $1 250 000 for hospital construction, Philadelphia could extirpate tuberculosis, and with a law imposing cumulative penalties for failures to report cases, in a period of say ten years could limit the city's death rate to that of general causes This is a small sum to pay for the ransom of a great city—for the saving of 3,000 lives a year and for the removal of a daily peril which menaces entire families and communities The annual cost of maintaining the proposed undertaking would be but two thirds that of the police, one third that of the schools, and but double the increase made to the city's salary list in 1907

Transmission of Tuberculosis.

DR W A EVANS, Chicago Tuberculosis is a disease of major sanitary importance It is transmitted through air and milk—the one universally used, the other very largely used The infected people and cows are difficult to handle, by reason of the chronicity of the disease including its slow disabling Air borne tuberculosis is spread in halls, cars, working places and other assembling places as well as homes Homes spread consumption by (a) being infected, (b) lowering vitality (1) determining infection, and (2) determining results of infection

Railway Surgeons Who Are Not Permitted to Have Passes

The Supreme Court of Nebraska says in the case of State vs Martyn, that the defendant a physician made a contract with a railway company to furnish all necessary surgical and medical treatment to the sick and injured employes of the railway company free of charge to said employes and also render such services to passengers and others for whom the company should request the same between certain stations in Nebraska for which he was to receive an annual pass on the Nebraska division of said railroad, together with trip passes on other divisions thereof and $25 per month during his employment The defendant was prosecuted for accepting pass in violation of law and it is held that the district court erred in directing the jury to find the defendant not guilty and discharging him from further prosecution The Supreme Court holds that a contract between a railway company and a physician by the terms of which he is to receive for professional services to be rendered by him for the comp [illegible]

30. **Arrhythmias of the Heart.**—James reports cases which show: 1, That complete heart block going on to a fatal termination is possible without the Stokes-Adams syndrome being present at any time; 2, that complete Stokes-Adams syndrome may exist in the presence of perfect atrioventricular conduction, an example of which condition has also been mentioned by Lépine; and 3, that there is another and closely allied syndrome, consisting of tachycardia in the presence of mitral and tricuspid regurgitation, associated with syncopal and epileptiform seizures. The physiologic end-result of these conditions is the same as in the Stokes-Adams syndrome, in that many systoles are lost through their being unable to open the aortic valves, while the physiologic origin is entirely different, being in the one case hyperrhythmicity of the atrioventricular bundle, and in the other a blocking of this structure.

31. **Subtemporal Decompression in Chronic Nephritis with Uremia.**—Cushing and Bordley report a case in regard to which they draw the following conclusions: In view of the marked improvement after cerebrospinal decompression, this case supports Traube's hypothesis that the cerebral symptoms present in the so-called state of uremia are largely due to pressure from edema of the cerebral tissue. It goes to show, furthermore, that the condition of so-called albuminuric neuroretinitis is, in large part at least, a local edema of mechanical origin. The case suggests the propriety of permanent decompression in selected instances of renal disease, when medical measures or lumbar puncture have failed to relieve existing cerebral (uremic) symptoms, or when blindness is threatened, owing to rapidly advancing degenerative changes of the nueroretinal tissues.

33. Abstracted in The Journal, June 13, 1908, p. 2019.

34. **Grocco's Sign in Pregnancy.**—Smithies points out that various observers have succeeded in obtaining a paravertebral dulness in extrathoracic affections—e. g., ascites, subphrenic abscess and multilocular cystadenoma in the abdominal cavity. From the last case Smithies was led to investigate whether similar areas of dulness might not be obtainable in cases in which the abdominal tumor was not pathologic, as in pregnancy. He reports seven cases. The patients were all primiparæ, with ages ranging from 16 to 22 years. Five were pregnant between the eighth and tenth month, one was about fifteen days overdue, and one was pregnant in the sixth month. In only two of the cases did percussion fail to demonstrate a well-marked area of dulness along the spine. The dull areas were roughly triangular, with more or less convex hypotenuses; and they were all to the left of the midvertebral line. In all cases, examination of the thorax was negative. The paravertebral area of dulness were not so distinctly triangular in outline as those that are percussed in cases of simple effusion into the pleural sacs. The hypotenuses appeared to be more markedly convex than in cases of effusion, and there was a tendency for the paravertebral dulness to be flat-topped. In two cases the hypotenuses were at a rather higher level than the point at which the line met the spine. Moderately strong percussion strokes were used to delimit the dull areas. The triangles were generally larger when the patients lay or leaned to the left, and rather smaller, although sometimes higher, when the patients leaned to the right. There were no definite auscultatory signs over the areas or over the lung adjacent thereto. There were two cases in which the paravertebral dulness could not be percussed on either side of the spine, in whatever position the patient was placed. The paravertebral dulness in pregnancy appears to be due primarily to the abdominal tumor.

35. **Overcivilization and Maternity.**—To Newell, the conclusion seems inevitable that a type of woman formerly very rare is now becoming relatively common. He illustrates this by three case histories. The working woman—the type usually seen in hospitals—generally goes through her pregnancy and labor as the natural process it is commonly supposed to be. With the overcivilized woman, on the other hand, either great variations from the normal are possible in individual cases, or differences in class and environment have developed new conditions which will eventually necessitate the development of a new procedure. Pregnancy entails in the latter a marked reaction in which nervous symptoms are most likely to be exaggerated. Faulty elimination and autointoxication are more common, the woman is unduly sensitive to outward influences and minor discomforts. She often comes to labor, consequently, in a condition physically unfit to withstand any serious strain. The convalescence is apt to be long and unsatisfactory and we have also to reckon with a nervous breakdown. Nursing is impossible, or if satisfactory at first, has to be given up in three months or so. The elimination of the unfit during infancy, more common in the poorer than the better classes, while doubtless a factor, can not alone explain the prevalent conditions. The city-bred girl of to-day, carefully shielded from undesirable surroundings, is brought up like a hothouse plant, lacking outdoor exercise and fresh air, is overstrained at school, and the strain continued out of school with the pursuit of accomplishments such as music practice, etc. Later, her hours are late and social engagements many, and even if athletic, the time spent on golf, tennis, etc., is taken from the rest period, during which the girl of a previous generation was recuperating from the strain of social obligations, balls, etc. It is necessary to take into consideration the need of change in methods which is entailed by this condition. If the patient is not only to be delivered alive, with a living child, but is to be brought through in such nervous and physical condition that she will be able to assume the function and duties properly belonging to her after convalescence, she must be watched through her pregnancy; and if, after due consideration, the obstetrician has decided that a certain patient will probably go through labor badly, immediate delivery must be undertaken, no matter what the stage of labor, at the first indication of unfavorable signs. When it seems absolutely certain that labor will be unsatisfactory, pregnancy should be ended at a set date by operative procedures, by the method least liable to result in injurious effects to the future health of the patient. Until recently in the absence of definite pelvic contraction or faulty relation between maternal and fetal parts, operation was limited to forceps or version. But the author says that in the case of an elderly primipara with rigid soft parts, the dangers of a pelvic delivery leaving serious after-effects are materially increased, and in these cases there is no question that abdominal delivery will probably give the best results. Cesarean section, performed before the beginning of labor under proper conditions and by a competent operator, is nowadays practically without danger to life or to health, and there can be no doubt that in many cases it offers distinctly the best chance for a proper recovery.

37, 39, 40. Abstracted in The Journal, June 13, 1908, p. 2018.

38. **The Pupil in Disease.**—Jackson says that much that ha-

been written about the pupil in relation to general disease, is mistaken and misleading. The pupil furnishes no pathognomonic symptoms of general disease and does not finally settle any doubtful questions of diagnosis. Nevertheless it is enormously suggestive to one who is on the lookout for clues, that may be followed up. He quotes Signorelli to the effect that inequality of the pupil usually indicates the side of the body on which the lesion is situated. He refers, as suggestive, to cases of pupillary dilatation situated on the same side as a pulmonary lesion. He considers the probable explanation to be an irritative effect of the pulmonary lesion on the sympathetic. Disease of the spleen and the arch of the aorta appear also to be connected with pupillary symptoms. It ought, he says, to be recognized that all abnormalities of the pupil not due to temporary causes, are suggestive of syphilis.

49 Proteolytic Enzyme of Human Milk. A. E. Austin, Boston.

42. **Recurrent Lymphosarcoma of Kidney.**—McConnell seems to think that the tumor described was in reality a hypernephroma that had taken on a fatty change accompanied by a limited malignant tendency.

44. **Meningococcus Septicemia.**—Duval reviews the literature and finds that the meningococcus has been isolated from the blood during life in a comparatively small number of cases, almost in every instance fatal, the body then showing some form of extrameningeal lesion invariably occurring in endothelial-lined cavities. General infection is probably always secondary to the diseases of the meninges.

45. **Nephrotoxins.**—Pearce and Sawyer confirm observations of Lindemann and others, that the serum of dogs with various types of nephritis has a toxic action on the kidney, but they have not been able to demonstrate any nephrotoxic power for the serum of rabbits with experimental nephritis. Consequently, the phenomenon should be used with caution in theoretical discussion of the nature of chronic nephritis.

46. **Hemolysis in Cancer.**—Weil's observations on the isohemolytic power of the serum in human cancer do not support the generalization made by Crile (THE JOURNAL, June 6, page 1883, and July 11, page 158), who regards the reaction as characteristic of cancer.. According to Weil, the method yields results of such a character that great caution and reserve must be exercised in their application to human diagnosis.

47. **Epidemic Influenza.**—Lord found the influenza bacillus present in overwhelming numbers in 25 per cent. of unselected cases of cough and expectoration during the interval between epidemics of typical influenza; but the bacillus was present in only 15 per cent. of the cases with clinical features of influenza during an epidemic. Hence the influenza bacillus, as pointed out also by other investigators, can not be regarded as the principal cause of influenza, but seems to bear the same relation to it as do the pneumococcus, pyogenic cocci, and *Micrococcus catarrhalis* to both epidemic and interepidemic cases.

53. **Sudden Death Following Injection of Foreign Blood Corpuscles.**—Coca summarizes his study from the Cancer Institute in Heidelberg as follows:

> 1. The cause of sudden death occurring within five minutes after the injection of relatively small amounts of the washed blood corpuscles of a foreign species, is a mechanical obstruction of the lesser circulation, produced by the lodgement of the injected cells in the pulmonary capillaries and arterioles.
>
> 2. The lodgement of the foreign corpuscles in the pulmonary vessels is probably due to an agglutination process.
>
> 3. The presence of specific agglutinins in the blood is not sufficient in itself to produce pulmonary obstruction on injection of the "toxic" corpuscles; an essential adjuvant factor must be assumed to exist in the blood-vessel walls.
>
> 4. Toxic substances have not been demonstrated with certainty as existing in active form in the fresh corpuscles.
>
> 5. The absorption of the specific agglutinins by the corresponding blood corpuscles takes place practically instantaneously.

57. **Prostitution.**—DeForrest details his personal observation of police methods of dealing with prostitution in Germany. He quotes examples of the various notices and warnings, the police regulations, etc., in Berlin, and details the method of examination and the service regulations controlling physicians in Dresden. He discusses the controversy between the abolitionists and the regulators, and reproduces Vorberg's statement of the claims of the two parties. He next discusses the report of the Committee of Seven in New York. He eliminates from the discussion the abstractions of the philosopher and the conclusions of the humanitarian, which are often impractical, and adopts the view of the physician. The following fundamental rules are essential:

> 1. The destruction of the source of the disease, so far as this is possible; and 2, the isolation of all persons affected with the disease from those of the community who are in good health. He refers to the movement recently originated in Iowa for placing venereal diseases on the same footing with other contagious diseases. It is impossible to frame laws that shall eradicate, or even control, sexual desire. Consequently, prostitutes will always ply their trade everywhere. It is probable, however, that even with the present laws on the subject, segregation of prostitutes could be enforced, and they could be driven out from the greater portion of the city to ply their trade only in restricted areas and under such conditions that all outward signs of immorality could be suppressed. The actual medical examination of such women would markedly diminish the cases of veneral diseases, but to make it effectual the men who consort with them should also be examined. The question is necessarily at present academic, wherefore DeForest urges education in sexual matters, both of elders and children.

66 Instrumental Uterine Perforation. A. G. Schlosstein, St. Louis.

63. **Development of External Genitals.**—Taussig enumerates and discusses the four main theories as to the development of the hymen: 1, The avulvar theory, according to which the hymen is a fold originating from the vulva or sinus urogenitalis; 2. the bilamellate, vulvovaginal theory, that one fold of the vulva and one of the vagina coalesce to form the hymen; 3. the unilamellate vulvovaginal theory, that one side of the hymen is composed of vaginal, the other of vulvar tissue, the hymen developing from the membrane left at the point where the Muellerian ducts enter the urogenital sinus. This is the one at present accepted by most anatomists; 4. von Dohrn's vaginal theory, that the hymen is formed after the breaking through of the coalesced Muellerian ducts into the urogenital sinus, and at a point further up in the coalesced ducts. Taussig has made serial sections, including the ex-

tire pelvic organs (illustrations of which are given in six cases), and finds that his investigations support von Dorhn's theory, but they involve the interpretation of certain structures that were not recognized by him and to a great extent they explain the divergence of opinion. He found that in embryos of 16 to 18 cms. length, at the point where the Muellerian ducts break into the urogenital sinus, there is at times a well-defined fold, such as is described by Nabel as the hymen. At this time there is no decided connective tissue proliferation. Immediately following this stage, in embryos of 20 to 22 cms. length, such proliferation takes place. One long fold of vaginal tissue projects just internally to the fold at the entrance, until the vaginal lumen is almost wholly closed at this time. This is not merely a fold, such as the one in the 16 cm. embryo was, but is a thick well-defined membrane. In later stages, 28 to 30 cms. embryos, the original fold can still be distinguished extending from the dorsal side of the vulvovaginal opening, but it is not proportionately very much smaller, so that it might readily be overlooked beside the fleshy membrane of vaginal origin lying further inward, the true hymen. There are at this time no secondary papillæ or folds, such as are to be found in the vagina of the full-term fetus, so that it could not be said that this structure which Taussig takes to be the hymen is merely such a secondary fold or papilla. It is a thick fleshy occluding membrane, the only membrane found. A further proof that it is purely vaginal in origin is the fact that even at birth it is lined on both sides by the same vaginal epithelium. The difference in the character of vaginal and vulvar epithelium is evident from the illustrations appended. The connective tissue fibers which go to make up the hymen are directly continuous with the vaginal connective tissue fibers, and are in no wise associated with the vulvar connective tissue. Finally, the hymen has papillæ on both sides, and the edges of its orifice or orifices are often irregular, as one would expect in a membrane resulting from a proliferative process, but such as one would not expect in a membrane resulting from a ring-like dilatation.

67. **The Sick Child.**—Rotch urges the importance of understanding that the infant and child are neither mentally nor physically the same as the fully developed adult. All the tissues, all the mental and physical conditions, differ widely between the first year and the second. The infant at birth is a mere automaton. Rotch describes the progress of development through the first, second and third years. With regard to children, he points out that the chronologic age is not necessarily the true age. It is the anatomic age which practically determines what the child can and should do mentally and physically without harm. Rotch urges the importance of a clear conception of the normal in the healthy infant and child. When one knows how the healthy infant or child ought to look and to behave, it will be easier to recognize how such individuals look and behave when ill. Illness is often overlooked on the ground that a child is spoiled; it is difficult to spoil a healthy child. The buoyancy, cheerfulness and good nature of young children come from a feeling of comfort and general vigor produced by healthy tissues and normal functions. The healthy child rebounds quickly from a cross word, while a sick child resents it and dwells on it. It is difficult to locate the source of pain in very young children and babies. The stomach is often blamed for reflex localized pains. Different children have different temperaments. Some have easily excited nerves, others quiescent nerves. Rotch discusses the confounding of dulness, stupidity, laziness, and other supposed mental conditions, with physical disease.

79. **Postoperative Gas Distention of Abdomen.**—Moenninghoff speaks well of the use of eserin salicylate hypodermatically in laparotomy as a prophylactic against distention. He gives 1/40 grain, immediately after the patient has returned to bed. Subsequent doses may be given but are rarely required. He has never seen any bad after-effects. He also has seen good results at the hands of Dr. H. E. Pearce from the application of a 500 candle-power leucodescent light, and considers Gelinsky's method of superheated air worthy of trial.

82. **The Roentgen Ray and Tuberculosis.**—Engelbach and Carman conclude that the *x*-ray examination is a valuable adjunct to the diagnosis of pulmonary tuberculosis for the following reasons:

1. Many of the indefinite anatomic conditions of the pleura are easily demonstrated positively.
2. The lesions of the third stage of tuberculosis (infiltrations and cavities) can be diagnosticated positively as to size, number and location.
3. The extent of known tuberculous lesions of the second stage (infiltrations and beginning lesions) are demonstrated more accurately than by physical findings alone.
4. Combined with the clinical and physical findings it affords valuable evidence in the diagnosis of a majority of the cases of incipient tuberculosis.

97. **Pelvic Diseases and Mental Disorders.**—Moody says that in considering pelvic diseases as causative factors in disea-

of the mind and nervous system, we must not forget to eliminate all such psychoses as the puerperal and lactational insanities, etc. These come under the head of infection or exhaustion or toxic psychoses, and occur frequently when no pelvic disease exists, in some women of a more or less profound neuropathic constitution, in others when menstruation is temporarily suspended for any trivial cause, and in yet others during the entire course of pregnancy at intervals corresponding to the menstrual periods. The cause of the nervous derangement in these cases can not be assigned to disease of a pelvic organ. It is merely due to the inability of the nervous system to withstand stimuli which, in a healthy individual, would result in normal physiologic changes. The psychoses and neuroses of the menopause are also to be eliminated. The menopause is not a disease condition, but a normal physiologic epoch, as is also pubescence. Each marks a physiologic transition which, in neurotic individuals, may create considerable shock to the nervous system. Many serious neuroses and insanities are precipitated at these periods of life, and those of puberty as frequently in males as in females. Masturbation in the female is no more due to a pelvic disease than it is in the male. Where there are preputial adhesions, or malpositions or adhesions of the clitoris or of other external genitals, their correction is of the greatest importance. Outside of these few instances of physical displacements and defects, masturbation in both sexes is a manifestation of a neuropathic condition, and its existence can no more be assigned to diseased ovary in the female than to a diseased testicle in the male. The radical treatment by ovariotomy is justifiable in the same degree as is asexualization in the male. Reference should be made to the possible effects of mental and nervous diseases on the female organs. Just as a lack of sufficient muscular tonicity in the intestines may cause constipation, and as a lack of general muscular tonicity due to nervous exhaustion may cause gastroptosis, gastric dilatation, strabismus, splenic displacement, etc., so will it cause uterine and ovarian displacement, endometritis, etc. Local treatment of any of these conditions will not cure the patients. In all these conditions the treatment of the local disease is secondary in importance to those measures which restore the nervous exhaustion, conserve nervous force and re-establish normal nutrition.

117 Angioma of the Orbit, with Invasion of the Globe Along the Ciliary Nerves. A. Quackenboss, Boston.
118 Recurrent Traumatic Erosion of the Cornea Due to Lachrymal Stricture. R. J. Curdy, Kansas City, Mo.

111. **Infections of the Orbit.**—Bull studies mixed pneumococcus and streptococcus infection of orbit and adjacent sinuses in a series of cases and emphasizes the following points:

The marked insidiousness of the attack, and the varying duration of the period of incubation.

The extreme violence of the symptoms in the sudden onset of the attack.

The very rapid rise of temperature and the equally sudden fall after operative interference has opened the purulent deposit.

The rapid development and violence of the symptoms point apparently to an unfavorable prognosis. Immediate and active interference, with free incisions, thorough curetting and irrigation, and prolonged and careful hunting for the purulent foci, soon bring about a more favorable condition.

The necessity for great vigilance in watching the cases and searching for new foci on any sudden and rapid rise in temperature.

The patients were all young, the oldest being 21 and the youngest 9 months old.

In only one case was the eye lost from suppuration.

113. **Interstitial Keratitis in Acquired Syphilis.**—Carpenter holds that the rarity of diffuse interstitial keratitis due to syphilitic infection is more apparent than real, because we are apt to overlook the possibility of acquired syphilis in young patients. He discusses the symptomatology, and points out that, contrary to the rule in the inherited form, the interstitial keratitis in acquired syphilis almost invariably attacks only one eye. The period of onset varies within wide limits, from three weeks to twenty-three years. Iritis and vitreous opacities, etc., well forward in the chorioid, though not unusual, are far less frequent than in the inherited type. He discusses the pathology, which is naturally somewhat indefinite, since opportunities of microscopic examination in keratitis of acquired syphilis are rare. This condition is a disease of adult life, occurring usually between the ages of 20 and 50, though it has been found in childhood and infancy. Next in etiologic importance to syphilis as a cause of interstitial keratitis is tuberculosis. Pflüger has reported thirty-six cases due to influenza. Interstitial keratitis due to acquired syphilis responds with remarkable promptitude to antisyphilitic remedies. The local treatment does not differ from that of ordinary interstitial keratitis—atropin, dionin, and rest of the inflamed organ, followed by massage with the ointment of the yellow oxid of mercury.

115. **Sympathetic Ophthalmia.**—Thomson reports two cases which terminated favorably and discusses the condition. He concludes as follows: For general administration, the drugs which resist plastic formation—the salicylates, mercury, potassium iodid and quinin—have been long advocated and continue to be our only hopeful line of treatment. The chief value of mercury is probably in cases with latent specific tendency, and, on account of the difficulty of excluding this, it is almost always wise to begin treatment by a vigorous exhibition of mercury by inunctions. The tonic value of quinin can not be denied, but personally Thomson has not had much success in its administration in this class of cases. It is difficult to give very large doses, the toxic effects are annoying, and he has always been in doubt as to its real value. Potassium iodid is of value principally in the later stages of the attack.

119. **Schoolrooms.**—Standish gives the following as the essential factors in the proper illumination of school rooms:

1. The walls should be painted a very light color, preferably an exceedingly pale green or buff.
2. The wooden finish of the room and desks should be light in color.
3. The window shades should be able to exclude direct rays of the sun, diffuse daylight freely, and also in the evening reflect a generous proportion of the light which falls on them.
4. Direct illumination is desirable.
5. The lighting stations should be so arranged that no annoying shadows shall fall on the pupil's desk.
6. The newer forms of incandescent lamps and Zalinsky shades, when properly arranged, can give a candle foot illumination of 2.5 on each and every desk in the ordinary school room; and finally,
7. In most cities the expense of electricity, used in the manner above described, is not so much greater than the cost of gas as to be prohibitive.

2. **Cretinism.**—McCarrison, as the result of an analysis of 203 cases, collected by house-to-house examination of almost every goitrous village in an area of 500 miles in the Himalayas, discusses the subject under the following heads:

1, The incidence of cretinism and its relationship to the incidence of goiter; 2, goiter in the individual and its relationship to cretinism; 3, goiter in the mother and its relationship to cretinism; 4, *debilitating factors* and their influence on the mother in producing cretinism; 5, types *of the disease* with associated symptoms. He draws the following conclusions:

1. The degree to which cretinism is associated with goiter is determined by the age of the endemic, and varies directly with the extent *to* which the *latter* disease prevails among the adult population.
2. Cretinism is rarely, if ever, due *to* the development of a goiter in the individual. The thyroid enlargement is, or may be, an effect: it is not the cause of the disease.
3. Defective thyroid function in the mother is the essential factor in the production of cretinism.
4. *Cretinism is due to the action of toxic* agents, notably that of endemic goiter, on the developing thyroid of the unborn child.
5. The thyroid defect is congenital, but it *may remain* latent pending its manifestations through the impulse of some accidental circumstance.
6. The defect in cretinism is one of the whole thyroid mechanism, of the parathyroids, as well as of the thyroid gland. The diversity *of symptoms* is *due to the* extent to which the defect bears on the whole or part of that mechanism.

3. **Tuberculin Treatment of Pulmonary Tuberculosis.**—Latham and Inman report further investigations, supplementary to their communication to the Royal Society of Medicine, *April* 1908, with regard to administration of tuberculin in pulmonary and other tuberculosis. They reach the following conclusions:

1. Tuberculin may be given with effect by the mouth or rectum or subcutaneously. The dosage is dissimilar, but animal experiments, opsonic curves, and temperature charts show that the effects produced are the same.
2. The administration of tuberculin meets with little, if any, success so long as successive autoinoculations spontaneously occur and can not be limited by the means at our command. Absolute rest is the most efficient means for limiting autoinoculation.
3. The administration of tuberculin may be adequately controlled in a large percentage of cases of pulmonary tuberculosis by a careful daily observation of the temperature and clinical condition of the patient on the lines indicated above.
4. In cases of difficulty valuable information may often be obtained from an examination of the opsonic index.
5. The German method of the routine administration of tuberculin by gradually increasing doses at stated intervals is not to be recommended. It is only satisfactory in a limited class of cases, and even then may not lead to the best results.
6. Tuberculin is a dangerous drug and its administration requires *considerable* experience. *It is capable, when given improperly, of* producing disastrous and even fatal results.

6. **Purin-Free Diet.**—Bryce says that the advantages of a purin-free diet are sometimes so notable as to arouse a tendency to uncritical enthusiasm. After a few years' experience one does not remain quite so sanguine as to its being a universal cure. He records cases of various conditions in which results have not been altogether favorable, and discusses the purin-free diet in this light with regard to periodical headaches, epilepsy, asthma, neurasthenia and various *other* conditions. He says that personal idiosyncrasy has much to do with the diverse results reported, and in his opinion, this is ultimately bound up with the *metabolic activity of the* cells, and especially the ability of the cells of the mucous membrane to withstand the onslaught of irritants, such as *purin* compounds. Small quantities of purin are almost invariably well borne, and only in isolated cases are larger doses not tolerated. The ability to tolerate purins is *markedly* influenced by disease—for example, neurasthenia, so called, and kidney ailments in which the integrity of the cells of *the* convoluted tubules is doubtful—yet a *man* in perfect health, with a so-called gouty *tendency may* tolerate them badly because they act as irritants to the mucous *membrane of* the hepatic ducts, and *produce* hepatic insufficiency.

9. **Home Treatment of Scarlet Fever.**—On the basis of an experience of many hundred cases of scarlet fever Milne is satisfied that the method of anointing the patient with 10 per cent. carbolic oil or eucalyptus oil day by day, and a plentiful supply of fresh air prevents the disease from spreading. After a few days his patients were allowed to mingle freely with other people. He reports many instances in which this practice has been followed—notably one in which he brought such a patient as a guest into his own home, allowing him to mingle freely with his children at meals and at games—without ill results. Milne now prefers eucalyptus oil which is rubbed in over the entire body from the crown of the head to the soles of the feet, including the roots of the hair, the axillæ and other flexures, both morning and evening for the first four days, then once daily until the tenth day. The throat is swabbed with carbolic oil, 10 per cent., every two hours for the first twenty-four hours. Milne has never known nose, ear or kidney trouble to follow, and the severity of the attack appears to be always mitigated. Cold must be avoided for three weeks and the children warmly clad. At first he allows only soda water or hot water and milk in equal quantities; in a few days he permits light diet, and by the tenth day ordinary meals. He has applied this method also in measles. This method, he asserts, dispenses with the need of elaborate disinfection afterward, the source of the disease being destroyed. Of course it protects only against contact infection and would not check an epidemic arising from a common source, such as infected milk.

11. **Cerebrospinal Meningitis.**—Holt reports 442 cases treated with the serum of Flexner and Jobling. He thinks that the evidence submitted must convince any candid mind that the course of cerebrospinal meningitis and its termination are distinctly modified by this treatment.

13. **Sanitation and Ankylostomiasis.**—Manson discusses the expulsion of the worm by thymol, beta-naphthol, eucalyptus oil in combination with chloroform and castor oil, the prevention of contact with foul ground, and the disposal of feces, which last he considers the only practicable method of effectively dealing with the disease as an endemic. In native villages and scattered communities he suggests that the responsibility for the observance of a latrine ordinance should be fixed on some local notable or official. As subsidiary methods he suggests:

(a) Making use of the local postoffices for the sale at cost price of anthelmintics, just as has been done so successfully in India in connection with quinin. (b) The scattering broadcast of leaflets or posters explaining in simple language the symptoms, nature, treatment and prophylaxis of ankylostomiasis anemia. (c) The teaching in schools by pictures and object lessons the natural history of the parasite and its effects and the importance of avoiding infection.

18. **Latent Malaria.**—Plehn discusses three phases in latent malaria and calls attention to urobilinuria as a symptom easily to be observed and indicating latent malaria after the disappearance of other signs. He uses Schlesinger's method, which is as follows: To the unfiltered urine add an equal quantity of a solution of 10 parts of zinc acetate in absolute alcohol in a test tube. Shake it well and add a few drops of Lugol's solution, stirring it again. Afterward the filtered mixture shows fluorescence more or less intensively according to its content of urobilin. Urobilinuria is not a specific sign of malaria but a symptom of liver disturbance. But in every case a strong urobilinuria after malarial infection proves that the organs have not yet recovered. It seems to be missing in the primary stage of latent malaria.

22. **Scurvy.**—Wright says that an examination of the dietaries of travelers whose supplies have been limited to certain articles and of those in great poverty who have tried to support life on tea and bread alone shows that a diet of meat and cereals or cereals alone produces scurvy, as do those foodstuffs which on incineration show mineral acids and especially phosphoric acid in excess over mineral bases. Such facts so far as they go would seem to suggest that scorbutic foods produce scurvy by introducing into the system excessive mineral acid. In cases of infantile scurvy examination of bone has shown that decalcification is going on, suggesting the presence of excess of acid or absorption or solution of lime salts. For the treatment of established scurvy the most direct mode is to administer the desired alkali in combination with an organic acid, e. g., sodium lactate. These substitutes are easily transformed in the blood into the corresponding carbonates. Another principle should be to replace the calcium and magnesium salts which may have been abstracted from the tissues. Reduction of the coagulability of the blood is present in this disease. This seems to contraindicate to some extent the use of lime juice and orange juice.

29. **Prevention of Tropical Liver Abscess.**—Rogers urges the reinstatement of the ipecacuanha treatment, 30 grains (1.95), or in less acute cases, 20 grains (1.30), of chloral hydrate. No food or fluid should be given for three hours before or after the dose. He compares the rejection of the ipecac treatment to the substitution, early in the nineteenth century, of venesection and salivation for the empirical quinin treatment, which was not restored to use again till 1847. Amebic ulcer of the great bowel is readily curable by ipecacuanha, and on this ulcer, Rogers holds, the liver abscess depends.

30. **Transient Heart Murmurs.**—West defines a murmur as "an abnormal noise heard between the heart sounds when nothing ought to be heard in health." He discusses transient aortic systolic murmurs, which are frequently due to excitement. This leads to temporary dilatation of the aorta with a consequent murmur which disappears as soon as the dilatation passes off. Hemic or venous murmurs and transient murmurs during chorea and rheumatic fever are discussed. He then raises the question of the so-called dilatation murmurs. He reviews the statement of Ludwig and Hasse, that the valves of the heart are not in health completely competent to close the orifices of the heart unless by means of the muscular contraction the orifice is first narrowed, and says that the statement rests on certain physiologic experiments of a very crude character, which, so far as he knows, have never been confirmed, and against which there is the strongest possible clinical evidence. He gives clinical reasons for the view that these murmurs are due to eddies set up within the dilated cavity itself.

41. **The Child.**—The phase of childhood between the ages of 2 and 7 is characterized by the fact that milk is no longer the most important food, and that certain parts of the nervous system are developing actively, especially those which preside over the motor functions and the intelligence. The will power does not become strong until later. This is the age for tracheo-bronchial glandular trouble, tuberculous meningitis, adenoid vegetations and the acute contagious diseases. After the age of 2. the *immunity transmitted by heredity* disappears and the child is less isolated. Children at this age are not more susceptible to contagions, but conditions favor them. The resisting powers are constantly growing stronger and the children generally recover completely from their acute infections. After the age of 7 there is a phase of slow growth until about 12, when there is a sudden and rapid growth up to puberty, but this growth is not harmonious. The trunk is relatively short and the thorax narrow, the heart small and the breathing capacity weak, in proportion to the height. In this period the natural conditions are identical with those which we regard as the "tuberculous constitution" It seems that the so called "candidates for tuberculosis" retain into later life the corporal proportions of the antepuberty period, *and do not grow into normal adult proportions.* Marfan asks: Is this arrest in the development a predisposing cause for tuberculosis, or is it not rather already the effect of latent tuberculosis? The diseases most common at the age of puberty are typhoid fever and acute articular rheumatism, with heart complications, and possibly chorea. Tuberculosis at this age is remarkable for the frequency of the torpid forms and of galloping phthisis, and the localizations in the peritoneum and lower extremities. The thymus has completed its involution and the tonsils commence theirs. Marfan adds that between 6 and 12 the mortality is the lowest for children. The child has paid his tribute to the acute infections, while the growth is slow and harmonious. During the antepuberty phase the child requires special hygiene and restraint from excessive exercise and fatigue. Attention should be paid to strengthening the will power during this period, and Marfan adds that the home surroundings are generally better for this age than most boarding schools. In conclusion, he discusses the question whether pediatrics should be made a specialty, saying that a physician who practices among children must know, to start with, all that a physician has to know who practices only among adults, and besides this, he has to study the childish organism throughout, its unfinished development and energy of growth inducing special characteristic reactions

44 *Therapeutic Action of Adrenalin Applied to the Skin (Action thérapeutique de l'adrénaline employée *en badigeonnage* cutané) G Sardou
45 *Cancer of Body of Pancreas (Cancer du *corps du* pancréas) A Chauffard.

44. **Therapeutic Application of Suprarenal Extract to the Skin.**—Sardou has found that a suprarenal extract applied locally to the skin has a remarkable effect on the tissues below, the constriction and following dilatation of the blood vessels modifying the circulation to such an extent that not only is pain relieved, but lesions are influenced and inflammation given a turn for the better These effects are not constant, and the intensity and persistence of the action of the suprarenal preparation vary with different tissues and decline with repetition. But even with these restrictions, he has succeeded in arresting or attenuating the pain in swollen joints, in contusions, in various processes in the bones, periosteum, and epiphyses, *congestive* headache, neuralgia, sciatica, rheumatic pains, traumatic joint affections and fractures and inflamed varices. Even the viscera feel the soothing effect, pain in the liver, kidneys, bladder, stomach and intestines being relieved, he asserts, by painting the surface with adrenalin, and spasmodic congestion subsides He has also found it useful in congestive suffocating spasms in an asthmatic and a nephritic, relieving the dyspnea. In a case of occlusion of the esophagus from cancerous growth permeability was restored by the action of the extract, and in a cancer of the breast the pain and swelling were much reduced, although the growth continued to progress. The effect was permanent in a case of old rodent ulcer of the face, the modification being so pronounced that subsequent Roentgen treatment completed the cure. In another case the "gymnastics of the blood vessels" induced by the extract allowed the reduction of a strangulated hernia which otherwise would have required surgical intervention, as also in a case of rebellious paraphimosis. It hastens restitution, he states, as for instance when a finger remains swollen and stiff after the healing of some lesion, the suprarenal extract banishes the pain and by reducing the swelling allows the finger to be exercised When there is no solution of continuity there is no danger of secondary hemorrhage, while the rushing back of the blood current has a most stimulating effect on healing processes, and also serves to ward off impending lesions

45. **Cancer of the Pancreas.**—Chauffard calls attention to a syndrome which allows differentiation of a cancer in the body of the pancreas and possibly encourages the hope that the lesion may be diagnosed in time to permit its successful removal. Even when the cancer is far advanced, operative intervention relieves the patient of the excruciating pain which is the predominant feature of this form of malignant disease, owing to the close connection between the body of the *pancreas and* the solar plexus Other features of the syndrome are the frequent desire for defecation—tenesmus of the entire colon—and rapid emaciation. It is rare for a tumor to be palpable, and the absence of jaundice, glandular involvement and of ascites is also striking in these cases There is no glycosuria, and the stools never showed much fat in the cases known. There is little if any vomiting, and jaundice does not appear until in the final stages, but the pain is deep and agonizing, resembling the gastric crises of tabes In the two cases described, the pain was at first on the left side; it lasted for several hours, recurring at intervals of eight or ten days. During the intervals there was no colic or diarrhea, but merely a vague sensation of abdominal tension and tenesmus. After a few weeks the focus of the pain shifts to the median line and then to the right side, and becomes more and more intense and the intervals shorter, and the patient complains of a constant sensation as if laced in a tight corset. One patient was a man of 37, previously healthy, until this sudden pain developed. An operation in the fourth month revealed the body of the pancreas studded with hard nodules, and a broken-down gland was found at the neck of the gall bladder which was drained The pain did not recur after the operation, but the patient succumbed in cachexia six months after the first symptoms. Another patient was a man of 40, previously robust. The patients can find no relief except by sitting bending far forward with the knees drawn up, to relax the abdomen. The resemblance to the gastric crises of tabes is so striking that in one case the cerebrospinal fluid was drawn by lumbar puncture to make certain that the patient was not a tabetic, although the constantly progressive character of the syndrome and the emaciation spoke against tabes. The initial pain on the left side is probably from radiation along the splenic nerves, but as the solar plexus becomes involved the pain assumes its typical median transverse and supraumbilical localization and its deep and excruciating character The syndrome differs completely from that of cancer of the head of the pancreas.

46 *Acute Tuberculosis of Typhoid Type. (La typho bacillose) L Landouzy
47 *Verdict of French Surgical Congress on Treatment of Facial Neuralgia J A Sicard

46 **Tuberculosis Simulating Typhoid.**—Landouzy states that his later experience has confirmed his announcements of twenty years ago in respect to a form of tuberculosis causing a typhoid condition with continuous fever and enlargement of the spleen, but without visceral localizations The fluctuations in the temperature are more irregular than in typhoid, the pulse is not accelerated, and there is no catarrh in throat

and bronchi as is constant in typhoid. The prognosis at the time is much more favorable than in typhoid, but it is far graver as to the future. The transition of the "typhobacillosis" into the pulmonary form with cavities, in the course of ten months of continuous fever, is not unusual.

47. **Treatment of Facial Neuralgia.**—Sicard comments on the increasing tendency to abandon intervention on the Gasserian ganglion for surgery of the roots and, still more, for local injections of alcohol. Destruction of the root at the base of the brain seems to be the only means of preventing recurrence.

48 *Astereognosis and Tactile Asymbolia. (Stéréoagnosie et asymbolie tactile.) F. Rose and M. Egger.

48. **Tactile Localization and Symbolia.**—A number of works on these subjects have appeared lately and Rose and Egger discuss them and report two cases, from Raymond's service, in which there was no sense of tactile localization, both patients having certainly some lesion in the brain. In another case a man of 33 presented typical pure tactile asymbolia. They conclude from their research that there is no case on record of pure primary tactile astereognosis except in infantile hemiplegia. The presence of astereognosis and asymbolia with slight sensory disturbances confirms the assumption of a cortical lesion.

49. **Treatment of Chronic Cardiospasm.**—Dilatation of the stenosis with an elastic water bag has been improved by Gottstein by making the bag less elastic and giving it the shape of a dumb-bell with a firm silk envelop. His illustrations show how the bag fits into the stenosis and stretches it as water is pumped into the bag. The effect is entirely different from that of the usual soft elastic bag, which bulges out above and below the stenosis without exerting pressure on the latter, except as it is pulled through the constriction. He describes six cases in which this forcible permanent stretching of the cardia by way of the mouth cured the spasmodic contraction. The first patient was a young woman who had suffered for four years from cramp-like pains and regurgitation of food with retention up to 100 c.c. in the esophagus. Transient benefit was obtained by the soft elastic bags, but the trouble constantly recurred until the inelastic "dilatation sound" was used. The cardia was thus stretched to 8, then to 10 and to 11.5 cm., which cured the condition permanently with no recurrence during the two years since. The second patient was a man of 37, and the history, the Roentgen picture and esophagoscopy showed the early stage of chronic cardiospasm with residuum of 10 c.c. Two applications of the "dilatation sound," stretching the stenosis to 11 cm., restored conditions permanently to normal. In the third case the symptoms had been noted for eighteen years and the patient learned to dilate the stenosis himself. In the three other cases the cardio-spasm was accompanied by great enlargement of the esophagus above. Two of these patients were entirely cured and the other was much improved. No mishaps were ever observed with the dilatation sound, and it can be used at the office. In none of the cases related it was deemed necessary to use an anesthetic, but if the stretching should prove very painful he would not hesitate to inject morphin, although the pain is a valuable means of control. The best results were obtained when the stretching was repeated several times at one sitting. He does not attempt to dilate the stenosis by pulling the bag through, but merely by increasing the distention of the strong bag.

52. **Plastic Resection of Old Stump to Restore Function.**—The Journal described, June 15, 1907, page 2079, Vanghetti's method of utilizing the stumps of the tendons and muscles for the functional use of the arm. De Francesco has been applying this technic in a case, five years after amputation, striving to make a "plastic motor" by this technic. The result confirms Vanghetti's assumptions and shows the errors to be avoided in such cases in future. The article is illustrated.

53. **Operative Treatment of Pulmonary Tuberculosis by Total Mobilization of Chest Wall.**—Friedrich thinks that comparatively little benefit results from resection of parts of the ribs. The wall of the chest must have all the bones cut away, without the least injury to the pleura, and this extensive operation he has performed in three cases with very promising results. In this "pleuro-pneumolysis" he resected nine ribs with a total of from 126 cm. to 163.5 cm. of ribs in each of the different cases. When the tuberculous process is forming cavities and is restricted mostly to one side, and the fever keeps up, the process progressing in spite of internal and climatic measures, or when a tendency to healing is evident, he recommends releasing the lung tissue to allow it to shrivel by this extensive mobilization of the chest wall above. The main factors in successful intervention of the kind are skillful anesthetization, the suitable position of the patient and rapidity of operation. The article is illustrated and various points in the technic are emphasized. The principal danger is in the behavior of the heart as it seeks to adapt itself to the new physical conditions in the chest. Friedrich has succeeded in keeping dogs alive after extirpation of one lung without inflammatory changes or development of adhesions between the pleura and pericardium. The large defect left after removal of a whole lung became compensated by displacement of the heart and mediastinum toward the defect, vicarious emphysema of the other lung, rising of the diaphragm and flattening of the ribs—all this without inflammatory cicatricial contracture. Especially remarkable in his dogs was the flattening of the ribs from the atrophy of disuse, thus making the thoracic cavity much smaller.

56. **Decapsulation of the Kidney for Chronic Nephritis.**—Gatti gives the history of this operation and reports its application in the case of a young man with Bright's disease who survived for twenty-eight months after the bilateral decapsulation. The general health showed marked improvement for twenty months so that the patient's earning capacity was restored, but then the old symptoms returned, the intervention not having permanently arrested the disease. A new capsule formed around the kidneys, but of compact fibrous tissue with few and small blood vessels.

58. **Treatment of Hydrocephalus in Small Children.**—Kausch reviews the experiences with 14 cases at Mikulicz's clinic, and discusses the various methods of operative treatment followed, comparing them with the experiences reported by others. The children were between 3 and 48 months old. The results of the surgical treatment were disappointing; transient improvement was observed but rarely, and the children usually succumbed soon after the operation. Complete success was realized only in one case. This patient was a child of 15 months with extreme hydrocephalus and spina bifida treated by a radical operation on the latter, with subcutaneous drainage of the meningeal sac. Kausch has been able to find on record 13 cases of recovery after operative intervention; in 6 cases the ventricle was punctured from one to seven times; in 4 cases lumbar puncture was repeated from three to twenty-five times; 2 of the children recovered under open drainage of the ventricle and his own patient under subcutaneous drainage of the lumbar subdural space. Anti-syphilitic treatment should always be tentatively administered,

both before and after puncture, as it does no harm in any case and may benefit, even in the non-syphilitic cases. Repeated puncture promises well, and he advises *alternate puncture of the ventricle and of the lumbar spinal cavity.* In puncturing the ventricle he would utilize the open spaces in the skull, avoiding the median line, or would puncture through a single drill hole, drawing less than 100 c.c. at a time from the *ventricle and 55* c.c. by lumbar puncture.

62 *The Lactic Acid Bacillus in the Digestive Tract and Its Relations with Functional Gastric Disturbances. (Vorkommen der sog. "langen Bazillen" im Verdauungstraktus und ihre Beziehung zu den Funktionsstörungen des Magens.) E. Fricker.

59. **Action of Hydrogen Dioxid on Secretion in the Stomach.**—Petri noticed that a 1 per cent. solution of hydrogen dioxid caused increased secretion of saliva when the mouth was rinsed with it, and experiments with it taken into the stomach show *that* it reduces the total acidity, especially the proportion of free hydrochloric acid. Its action in this respect is approximated only by that of oil, which it far surpasses. He gives the details of eleven cases in which it was tested, after establishing its absolute harmlessness on himself and others. The free hydrochloric acid can be reduced to zero, but it is a question whether this is the result of restriction of the secretion of acid or of increased production of mucus. When it is used to reduce the acidity within normal bounds, he advises giving the dioxid like a mineral water, in the morning, fasting, 1 to 3 parts in from 200 to 300 c.c. water. Or it can be used in a 0.25 or 0.5 solution for rinsing the stomach in case of hyperacidity and acid fermentations. The therapeutic use of the dioxid promises to render good service in cases of hyperacidity, hyperchlorhydria, ulcer, spasm of the pylorus, etc. It is possible that it might have a favorable influence also in hemorrhagic conditions, as it has been found useful in this line in epistaxis and uterine hemorrhage.

60. **Changes in Chemistry of the Stomach After Gastroenterostomy.**—Schönheim has examined five patients after gastroenterostomy, the findings confirming in every respect the results of Katzenstein's experimental research in this line. It is evident that the gastroenterostomy not only puts an end to the motor disturbances, but it also improves the conditions in regard to secretion and the chemistry of the stomach. His findings indicate that the operation should be considered in cases of obstinate hyperchlorhydria, even without stenosis of the pylorus and ulcer. In nearly every case after gastroenterostomy there is regurgitation of bile and pancreatic juice into the stomach. They appear even in half an hour when the food contains much fat. The alkaline intestinal juice reduces the acidity of the gastric juice by a chemical reaction, *while the pepsin* becomes inactive in the alkaline medium, but the trypsin remains active even in a weakly alkaline medium. It is possible to eliminate the hydrochloric acid entirely and thus to promote the healing of a gastric ulcer. This can be accomplished by frequent meals, much fat in the food, and copious ingestion of water. Although gastroenterostomy thus responds to the indications for causal therapy of gastric ulcer, yet internal treatment should be tried long and carefully, and only when the gastric ulcer shows no *tendency* to heal should *operative* treatment be advised.

62. **Lactic Acid Bacilli in Digestive Tract.**—Fricker has found lactic acid bacilli in the mouth, esophagus and intestines, as well as in the stomach. In *examination* of 148 patients with normal or increased acidity and normal or reduced motility, a few lactic acid bacilli were found, but the granulose reaction could only rarely be obtained, *and* tests for lactic *acid* were always negative. The findings were approximately the same in 31 cases of much-reduced acidity but normal motility. In 15 cases of carcinoma of the stomach with entire absence of free hydrochloric acid, lactic acid bacilli were found constantly, giving the granulose reaction, and lactic acid was also present in large amounts. Under normal conditions the stomach empties itself of fluid and solid content, including the saprophytic micro-organisms. Contrary to the other saprophytes, the lactic acid bacilli are unable to proliferate, even when there is *stagnation of stomach content,* unless there is disturbance in the production of hydrochloric acid. The discovery of large numbers of lactic acid bacilli, therefore, justifies the *assumption of reduced production* of hydrochloric acid and reduced motility; these conditions are encountered with cancer, but also with some other stomach disturbances, consequently *these bacilli have no pathognomonic significance.* It is much easier to detect these bacilli than to obtain the chemical lactic acid reaction, as the scrap of stomach content in the eye of the *sound will suffice for microscopic examination.* In four cases described in detail, the bacilli vanished after pylorectomy for incipient cancer, although the chemical functions remained *unchanged. As there was no ulceration* of the cancer, the Weber blood test and the Salomon albumin serum test *gave* negative *findings.* In another case the positive bacteriologic *findings* were *explained* by discovery of numerous lactic acid bacilli between the carious teeth. The stomach findings in this case were normal, the cancer being at the *sigmoid flexure. This case shows that when lactic* acid bacilli are found in the stomach content and the chemistry of the stomach is normal, the bacilli originate at some point above in the alimentary canal.

64 *Influence of Pleuritic Effusions on Course of Pulmonary Tuberculosis. (Einfluss pleuritischer Exsudate auf den Verlauf der Lungentuberkulose.) R. Konzelmann.

64. **Influence of Pleural Effusion on Pulmonary Tuberculosis.**—Konzelmann is able to add 8 more cases to those on record in which a tuberculous process in the lungs healed under the influence of a pleural effusion. In 26 cases a favorable influence from the effusion was marked in 16; 3 of these patients were in a group of 9 cases of advanced bilateral processes. The influence of the compression from the effusion was evident in the subsidence of fever, reduction of expectoration and improvement in the general health. In all but 2 of the 16 cases showing a favorable influence the patients' earning capacity was fully restored and has remained thus to date, in 8 cases during an interval of from one to *nearly* eight years. All these patients belonged to *the working classes and* the conditions were not *hygienically* favorable. One of them is a driller of holes in a locomotive *factory,* another is an iron cutter. The influence from the *effusion* is *generally unmistakable,* although the effusion was absorbed in two or three months at longest, with the exception of one case. Even after the disappearance of the *effusion,* respiration in the lung evidently proceeded less vigorously, and thus the lung was given comparative rest. The 26 cases are described in detail; the results *encourage* treatment of certain cases of pulmonary processes by artificially inducing a pneumothorax. The communication issues from a Zurich sanatorium, in *charge of* Staub.

Beiträge zur klinischen Chirurgie, Tübingen.

LIX, Supplement, pp. 1-220.

65 *Report of Heidelberg Surgical Clinic for 1907. A. Narath.

65. **Progress in Surgery.**—Narath reviews the work of the surgical *clinic* last year and expatiates on the progress realized by the more extensive use of local anesthesia. A 1 per cent. solution of novocain, with addition of a *little suprarenal* preparation, is used for the local anesthesia, and this allows a constantly increasing proportion of operations to be done without admission to the hospital. He says *that* any one who has had experience on his own body of the faultless action of the novocain-suprarenal anesthesia is sure to become its enthusiastic advocate and to regard *it* as *malpractice* thereafter when general or spinal anesthesia is used in cases for which local anesthesia would have sufficed. The *ether-drop*

method is given the preference for general anesthesia, usually preceded by small doses of morphin and scopolamin. The latter were also found useful as a preliminary to local and spinal anesthesia.

69 "Insufficiency of the Spine" and Scoliosis. (Insufficientia vertebræ und Skoliose.) A. Schanz.

66. Complement-Binding Test in Various Infectious Diseases.—The Wassermann technic was applied in 9 cases of measles. 5 of varicella and 14 of pertussis—all in infants—with invariably negative results. In 10 cases of scarlet fever the reaction was positive in 5. The positive findings were obtained only during a certain period in the scarlet fever, and only with certain extracts which seemed to possess the power to bind the complement in the serum of scarlet-fever patients as well as syphilitic serum. In 27 cases of manifest inherited syphilis, 25 of the infants gave a positive response. The reaction was constantly negative in 10 infants free from any sign of syphilis, while it was positive in 30 out of 68 cases suspicious of syphilis, including the 25 infants with manifest syphilis. In 4 other cases the infants had previously showed signs of syphilis which had subsided under treatment. The infants examined were in an orphan asylum and thus under constant observation for a long time.

68. Measurement of the Blood Pressure in Chronic Nephritis.—Engel pleads for the more general use of the tonometer as sufficiently accurate for general practice, while it affords most useful information for diagnosis and prognosis, and is a guide for effectual treatment. Uremic disturbances are frequently revealed by a sudden rise in blood pressure before they become evident in any other way. In nephritis with the parenchyma mostly involved a rapidly rising blood pressure, without signs of uremia, warns that the heart is failing. As the heart action is improved, the blood pressure drops. The former assumption that chronic parenchymatous kidney lesions are accompanied by nephritic hypertension is erroneous, the result of confusing it with cardial hypertension. In case of contracted kidney, a sudden pronounced drop in the high blood pressure indicates the giving out of the heart. He thinks it probable that every interstitial nephritis is nothing more than a localized arteriosclerosis in the kidney. Arteriosclerosis in time always leads to nephritis; in distinction from this secondary arteriosclerotic nephritis. true contracted kidney can be regarded as a primary arteriosclerotic nephritis, and high systolic blood pressure is an essential symptom of contracted kidney.

71. Recent Progress in Knowledge of Etiology of Diabetes.—Blumenthal comments on the discovery of the substances in the pancreas which activate the destruction of sugar by the ferments, and regards the lack of these substances as the primal cause of diabetes, although the final demonstration of this has not yet been given. The nervous system can also be regarded as participating in the etiology of diabetes as the central organ regulating all the metabolic processes. The muscles can also be regarded as a diabetogenetic organ, as the oxidation of sugar takes place principally in the muscles. If the functional capacity of the muscle for oxidation of sugar suffers for any reason, hyperglycemia and glycosuria are the inevitable result. Sugar is formed in the diabetic from the carbohydrates and from the albumin, and the amino acids are an important source for the production of sugar from albumin. The formation of sugar from fat has not been proved or disproved to date, but the production of acetone from albumin is now an established fact. As the albumin bodies are destroyed, carbohydrates are produced, which thus provide material that powerfully promotes the oxidation of acetone in the body.

72. Functional Diagnosis and Treatment of Heart Affections.—Strubell has been making a special study of the elasticity of the vessels to determine whether increased resistance offered by the peripheral vessels is of a transient, vasomotor nature or permanent from angiosclerotic changes. The warm bath is often valuable for deciding this question, as also for treatment. In case of pronounced arteriosclerosis, a warm bath of an hour's length will relieve the heart of a fifth to a third of its work during this hour, which is a great relief for the overburdened organ. The success of the warm bath in severe angiosclerosis has been actually startling in his experience, he says, adding that the physician who makes a systematic study of the blood pressure in his cases of angiosclerosis, is able to diagnose the condition from ten to twenty years earlier than physicians who neglect this important aid for early diagnosis. His arteriosclerotic patients are thus much younger than those of the older school, and he does not fear rupture of a vessel in the brain at this early stage from these warm baths. especially as he follows the warm—not hot—baths with a very hot foot bath to ensure diversion of the blood from the head. The delay and incompleteness of the drop in the blood pressure in the bath form the index for the capacity of dilatation of the blood vessels. Another important means of obtaining information in regard to the heart is afforded by determination of the ability of the heart to respond to nerve stimuli. For this purpose a weak alternating electric current is passed through the patient's body as he sits with dilated blood vessels in the warm bath, the entire surface of his body serving as the electrode. The electric current induces contraction of the vessels, and this is followed by an improvement or insufficiency in the heart action according as it is capable of normal functioning or not. With the normal heart the blood pressure rises, while the auricular pressure subsides. but with a pathologic heart the reverse is observed, the blood pressure drops while the auricular pressure rises. The test is similar to Basch's irritation of the exposed sciatic nerve in the dog, and gives important differential information. although it must be managed with great caution. The Roentgen rays show functional and anatomic changes in the heart before they are perceptible by percussion. The more we learn in regard to the heart. the more complex its functions are seen to be. We can already enumerate twenty-four kinds of influences, exclusive of the nerves. He regards as a great progress the graphic registration of the electric phenomena which accompany the contractions of the heart muscle, especially when recorded with the string galvanometer. He gives a number of tracings of these electrocardiograms, comparing the normal with various pathologic findings. They reveal at a glance the existence of neurasthenia and other characteristic abnormal findings. and allow an oversight of the heart functioning never previously attained.

73. Chondrotomy for Apical Tuberculosis.—Harrass warns that the severing of the ossified costal cartilage to mobilize the wall over an apical process has little prospect of successful outcome if the rigid cartilage is accompanied by a primary malformation of the first ribs showing that the trouble is the result of defective development in the first place. If there is much scoliotic asymmetry of the opening of the thorax the chondrotomy is not of the slightest use. If done under these conditions it merely throws discredit on Freund's operation for relief of an incipient apical process. It is indicated when central or peripheral ossification of the cartilage is observed with an incipient apical tuberculous process, or when the cartilage is primarily abnormally short and systematic exercises in deep breathing fail to improve the defective function. In every case it is important to determine with the Roentgen rays the exact conditions in the opening of the thorax, and in future the published reports should be accompanied by the skiagram of the opening.

75. **Cystoscopy and Catheterization of the Ureters in Children.**—Portner advises restricting these measures to the cases in which they are really indispensable, not resorting to them when there is no pathologic sediment in the urine, no matter how pronounced the bladder or kidney disturbances, nor in cases in which hematuria is accompanied by tube casts or by hemorrhages elsewhere, *showing that it is merely one manifestation of a hemorrhagic diathesis or a nephritis.* They are also contraindicated in cases of pyuria in which progressive improvement is observed under treatment. If the diagnosis is still wavering after four weeks in cases of hematuria and pyuria, then it should be made certain by cystoscopy or catheterization of the ureters as needed. They are both applicable for girls after they are a year old, and cystoscopy for boys after the second year. Catheterization of the ureters is scarcely possible for boys under the age of 8. The cystoscopic examination is free from danger, but requires general anesthesia; the bladder reflex persists even longer than the corneal reflex. The catheterization of the ureters should be supplemented by the usual functional tests of the kidneys, as for adults. He describes nine cases to show the benefits of these measures in dubious cases in children. His little patients were from 2 to 13 years old. The youngest patient was a boy with a large stone in the neck of the bladder. The cystoscope was introduced readily after slitting the external orifice. On the whole, he states, children display an extraordinary tolerance on the part of the urethra and bladder to instrumental intervention. Reports from various lands emphasize the rapid and prompt recovery of children after operations for removal of stones. This tolerance is in marked contrast to the slight resistance offered by children to certain other operative measures.

76. **Tumor in Child's Bladder.**—Rumpel reports the removal of a conglomerate of myxofibromas from the bladder of a boy of 3. There is no hemorrhage with these tumors, as the mucosa is not involved. Retention of urine is the main symptom.

Jahrbuch für Kinderheilkunde, Berlin.

81 Physiology of Growth and Development of Child's Organism. (Zur Physiologie des Wachstums und der Entwicklung des kindlichen Organismus.) A. O. Karnitzky.

78. **Anemia in Young Children.**—Scheible reports a case of probable hemophilia in a child of 2. The anemia from the repeated losses of blood was combated by injection of from 10 to 18 c.c. of defibrinated blood from healthy adults. The improvement under these injections was pronounced and striking, and the restoration of normal conditions in the blood was accompanied by improvement in the general health. Five of these injections were made in the course of six weeks. It is useless to attempt this transfusion of blood, he says, when the blood-producing apparatus is irreparably injured. It should not be done as a last resort, but should be tried as early as possible when anemia in children is assuming a grave form. The injections were made under the skin of the thigh. Some substance in the serum evidently acts as a stimulus for the blood-producing organs.

80. **Brain Findings in Children with Inherited Syphilis.**—During the last two years Weyl has examined the brains of six children with inherited syphilis who lived from two weeks to five months. There were no clinical symptoms of brain trouble, except in one case, but in every one the pia was found abnormal at different points, with thickening or infiltration. In five cases large numbers of typical lymphocytes were found in the pia. In the case with the most lymphocytes there were no signs of bronchitis. In all the children the morbid changes in the pia showed numbers of large round cells; in three cases the brain below was also affected.

86 Negative *Experimental Research on Duodenal Glycosuria.* A. Visentini.

82. **Cutaneous Reaction to Tuberculin in Infants.**—Ellenbeck applied v. Pirquet's test to 232 infants and obtained a positive response in only 5, 3 of whom died later, and the presence of tuberculous lesions was confirmed by autopsy; 2 are still alive, but with unmistakable tuberculous processes. Tuberculosis was discovered also in some of the 20 infants who died after a negative reaction, but the tuberculosis in these cases was in the advanced stage in which the reaction is inevitably negative. He commends the cutaneous reaction as harmless, simple and reliable, proving sometimes the first sign of latent tuberculosis. Negative findings are conclusive only when the test has been repeated several times at two-week intervals.

83. **Pernicious Anemia.**—Continuing this symposium, v Jaksch states that the similarity of pernicious anemia to kala-azar suggests a protozoon infection. He adds that treatment by the Roentgen rays or high-frequency current may possibly yet prove effectual; drugs hitherto have had little influence. Grawitz reaffirms his idea of intestinal intoxication as the cause of pernicious anemia in the majority of cases. The prospects of a cure in this form under dietetic and medicinal measures are very good. Schultze states that Fowler's solution has given long-continued improvement in some cases in his experience. In one case an improvement bordering on a complete cure was obtained with Levico water. This patient was an elderly man.

84. **Tetany with Autopsy Findings.**—Berger's patient was a woman of 29 who had had recurring articular rheumatism before puberty at 17. At 18 a large goiter was operated on; it required operation again eleven years later, and tetany followed, constantly increasing in intensity, the attacks being accompanied by loss of consciousness. The emaciated patient succumbed in a few weeks to a mild intercurrent diphtheria. The autopsy findings showed the characteristic changes in the nervous system, degeneration of the cells of the anterior horns, etc.

93 Rapid Surgical Roentgen Photography. L. Gilmer.
94 *Some Unusual Cases of Syringomyelia and Dystrophy. (Klinische Kasuistik aus der Praxis.) W. Erb.

87. **Immunity to Tuberculin.**—Hamburger states that the artificially acquired immunity to large doses of tuberculin is in many cases merely the result of inability to react on account of the saturation with antibodies. He describes two convincing tests, one in a babe of twelve months with autopsy findings. The individual seems to be rendered immune, when in reality the lack of response is merely an inability to react.

88 **Serum Treatment of Surgical Tuberculosis.**—Strauss has tried the Marmorek serum in 37 cases of various tuberculous processes in the bones, glands or bladder. He found it harmless and his general impression was favorable on the whole for its use in surgical tuberculosis.

90 **Serum Treatment of Meningitis.**—Orth has used a polyvalent serum in two cases of epidemic cerebrospinal meningitis, and gives tracings showing benefit from its administration. The injections were followed by an interval of general improvement during which the organism could reassemble its defenses. No complications have been observed in these cases during the fifteen months since.

91 **Giant Tumor of the Scalp.**—Klostermann reports the successful removal of a fibrosarcoma from the right side of the head. The growth measured 9x12x20 inches in circumference. It had evidently started as a cavernous angioma but had become malignant after the menopause.

94 **Dystrophy and Syringomyelia.**—Erb gives the details of about half a dozen cases of these affections differing in several respects from the classic types. In one case the progressive muscular dystrophy was confined to the legs and the affection had been erroneously differentiated by a number of prominent physicians, some ascribing the trouble to neurasthenia or tabes or compression of the spinal cord. The patient was a banker of 37. Erb in describing this case reiterates that only careful study of the history will protect the physician against serious error in these obscure cases. In another case the dystrophy was localized in the muscles in the back of the neck. Although of the juvenile form, the affection in this case commenced at the age of 50. In all his experience he had never witnessed a case of recovery from progressive muscular dystrophy and did not believe in its possibility until convinced of the contrary by a case in a girl of 7, and Marina has recently reported a similar case. In Erb's case the child presented a typical dystrophy of the juvenile form. The parents and brothers of the little patient are healthy. Systematic treatment was instituted and kept up for a long time, the galvanic current to the spinal cord in the neck with galvanofaradization of the muscles, gentle massage and exercise, iron, arsenic and cod liver oil, brine baths and fresh air, and the results were surprisingly good. In three years the child was entirely healthy and well grown with only a few traces of the former dystrophy. The last muscle to show traces of dystrophy, the deltoid, had developed normally, especially under the influence of swimming, and the child is now, six years later, practically cured.

104 *Pathology and Anatomy of Scorbutus. T. Sato.

100 **Experimental Hyperemic Treatment.**—Walther reports extensive experimental research with Bier's constricting hyperemia applied to rabbits' ears. The results can not be considered as favorable and his review of the literature has shown that streptococcus phlegmons are unusually resistant to this form of treatment. He took the streptococci from puerperal processes.

103 **Tumors of the Heart.**—Karrenstein has collected from the literature 39 cases of tumor of the heart exclusive of myxomas, and 38 of the latter. The details of the various cases are given and a case of myxoma personally observed is reported in detail. His patient was a man of 56 and the myxoma was located in the left auricle. None of the cases on record allowed a clinical diagnosis during life. The myxomas were found in the left heart in 27 of the 38 cases. The secondary tumors were much more frequent in the right heart, but other primary tumors occur in about equal numbers left and right. These heart tumors have been discovered at all ages. The myxomas were located on the tricuspid valve in 29 per cent. of the cases, but other forms of tumors only in 7.7 per cent.

104 **Scorbutus.**—When Port Arthur capitulated in 1905, the Russian sick and wounded numbered about 17,000, and more than half of these suffered from scorbutus. On account of this remarkable opportunity for research on scorbutus, a commission of five physicians was appointed by the Japanese to study this disease and Sato and Nambu here publish the official report of the commission. It includes an account of experimental research.

112 *Long Freedom from Recurrence After Incomplete Operation for Uterine Cancer. (Unerwartete Rezidivfreiheit nach unvollständiger Operation des Gebärmutterkrebses.) K. Fleischmann.

106 **Lancinating Pains in Head in Tabes.**—Lang calls attention to the pains resembling neuralgia which are liable to be encountered in incipient tabes. The pains follow the usual routes of neuralgia, but the nerve trunks are very little, if at all, sensitive to pressure, while severe sensory disturbances are generally evident. Another feature of this pseudoneuralgia is that the trigeminal and occipital nerves are generally affected simultaneously or alternately, which is rare in true neuralgia. Another means of differentiation is the inefficacy of ordinary treatment for neuralgia. His first patient was a woman of 46, who, nine years before had suffered for weeks from intense left headache. After an interval of some years the headache returned in the left side and the trigeminal nerve was resected, as no improvement was observed the Gasserian ganglion was taken out. The agonizing headache still continued in paroxysmal exacerbations, but pressure on the nerve trunk was nowhere painful, notwithstanding the intense pain in the trigeminal and occipital domain. Hypalgesia in the thorax and anomalous reflexes confirmed the final diagnosis of tabes. He describes further seven more cases, out of a much larger experience, all with these lancinating pains in the head as the first sign of tabes.

110 **Gynecology at Vienna.**—Schauta's address is accompanied by an interesting chart showing the mortality of the Maternity for the hundred years ending 1884. The curve shows the increasing mortality with the increasing anatomic tendency of medicine in the eighteenth century, especially when the material was used for teaching purposes. Then came Semmelweis and the curve drops from its highest point nearly to its lowest, then the level drops lower still with Lister, and reaches its minimum with the construction of a new building in 1873. Rosthorn devoted most of his address to the clinical consideration of pain as a symptom. The parts of the sexual system covered with peritoneum are devoid of sensibility to pressure, warmth, cold and pain and are refractory to stimuli, chemical, thermic and electri

—all this justifying the conclusion that in these parts it is innervated by the sympathetic alone. The uterus can frequently be extirpated without any anesthetic, with scarcely the slightest pain. Only considerable traction on the ligaments and severing the masses of connective tissue around the cervix, above the roof of the vagina, induce pain. The ovaries and tubes also can be cut and cauterized without the patient feeling pain. She notices the manipulations only when the pedicle of the ovary is pulled or ligated. Plastic operations on the vagina do not require even local anesthesia, if the orifice and the perineum are not involved. The sacral pain accompanying most gynecologic affections is undoubtedly a radiated pain, possibly explainable by Head's projection, but it occurs also in neurasthenics and hysterical patients free from gynecologic changes. It may also accompany displacement. It is important, he added, to classify the pain, and sometimes several days' observation are required for this, to study the factors which elicit the pain, intensify or attenuate it. Pain, he declares, confronts us in many forms like an all-conquering demon, and yet it is the friend of the sufferer, the watchdog of health. It compels the sufferer to seek help, and is thus the physician's most loyal ally.

112. **Freedom from Recurrence After Palliative Operation on Uterine Cancer.**—Fleischmann's first patient was a woman of 35 who is in good health eleven years after vaginal extirpation of the carcinomatous uterus, leaving a large part of the intestine involved in the growth. In two other cases the patients are still in good health ten and eight years after a similar incomplete vaginal operation. These cases confirm the view that it is possible for the organism to destroy or keep in a latent state a certain amount of cancer germs left behind.

122 *Paroxysmal Tachycardia. A. De Blasi.

120. **Experimental Study of Quinin Prophylaxis.**—Graziani made a daily subcutaneous injection of quinin in rabbits and guinea-pigs in doses proportional to their weight corresponding to the dosage for quinin prophylaxis of malaria. The injections were kept up until the animals were fully grown, that is, for three months, and in adult animals for the same length of time. The quinin evidently checked the growth a little and rendered the animals less resistant to infections, but did not seem to alter the composition of the blood.

122. **Paroxysmal Tachycardia.**—One of De Blasi's two patients was a physician, and in both the attacks of heart disturbance were separated by intervals of complete health. The heart muscle seemed to be absolutely intact under the most careful examination. The neurosis is apparently the result of chronic gastrointestinal disturbances. The attacks are sometimes brought on by stooping to pick up something, and are arrested by reclining or by an ice bag to the heart, inhalation of amyl nitrite or injection of morphin. Holding the breath also helps.

Original Articles

THE TREATMENT OF LOCOMOTOR ATAXIA.

ALLAN McLANE HAMILTON, M.D., F.R.S.E.

NEW YORK.

As a rule there is a disposition on the part of physicians, particularly specialists, who diagnose locomotor ataxia, to give a prompt and unfavorable prognosis, and to dismiss the patient with a few words of gloomy advice and perfunctory pity. It is for this reason that the victims of this serious disease of the nervous system fall into the hands of quacks and irregular practitioners, who promptly proceed to suggest and try fanciful remedies, and empty the pockets of a class of patients who grasp too readily at therapeutic straws.

To those who see much of this and like diseases it is a patent fact that there is always a liability to suggestion which seems almost characteristic and inseparable from the condition of invalidism.

An apparent improvement attends the administration of any new remedy, especially if it possesses novelty and is invested with a mystic import. For this reason one individual who has been in the local courts has made a large fortune from "magic" boots, which are sold at enormous prices, while a vast number of sheep and goats have contributed a part of their genitalia for the production of an equally profitable lymph. For a time all such invalids declare in triumphant tones that they are getting well and that the regular physician is an ignoramus. Sooner or later, however, the novelty ceases and there is a relapse. An experience of a great many years has made me familiar with all this, and I have been impressed with the wisdom of antagonizing the quack and working as long and faithfully as possible for the patient's welfare, although the outlook is often discouraging. I think this is also the view of my friend, Dr. Dana, who has had unusual therapeutic success.

Two classes of cases present themselves. One includes about 60 per cent. of all patients in whom there is a specific cause, and in whom the tabes is due to a parasyphilitic infection. This is progressive and usually incurable, but even this may be greatly modified if not arrested by intelligent treatment. The cases that form the other 40 per cent. are not only greatly helped but often cured.

Of course the existence of arthropathies, lost reflexes and atrophy of the optic nerve indicate neural disease that has gone on to actual destruction; but there are other symptoms which if treated with appropriate remedies will repay all the efforts of the physician.

Bearing in mind the luetic causation of so large a proportion of cases of tabes, we naturally turn to the use of one of the two universally used drugs that are available to combat specific disease of all kinds; but it must be admitted that only in a very small proportion of examples of tabes, as well as other organic nervous disease due to parasyphilitic causation, does the use of mercury and the iodids do any natural good. In fact, it has been often alleged that specific treatment is apt to do harm. In a small number of suitable cases, say 20 per cent., the employment of the former especially is serviceable. In some patients the disease develops very rapidly, and the early stage merges quickly into the second in such a way as to suggest the energetic activity of a syphilitic toxemia. I have known many such cases in which, within two years after there were recognizable initial symptoms, there would be well-developed ataxia. In other cases, in which there were attacks of paralysis of the ocular muscles, the exhibition of iodid or the use of inunction would prove of the greatest service almost immediately.

Again, in the mixed types it is clearly indicated. In this connection I may refer to a patient who had his initial sore six years ago, and in whom no symptoms of any kind developed until the spring of 1908. There were then vague, fulgurating pains, Argyll-Robertson pupils, loss of knee-jerks on the right side, and a static ataxia. There were no bladder symptoms, but there was constipation. One month ago (October, 1908) the patient came to me. He was then able to walk but in a disorderly way, there being no true locomotor ataxia. Two days after his arrival there was complete loss of power in both legs, loss of both knee reflexes, exaggerated plantar reflexes, increase in tactile, pain and thermic senses, no incontinence of urine but frequent priapism, inequality of the pupils and no reaction to light. The patient was immediately put on an inunction of mercury, large doses of iodid and ergot, with the result that in two weeks there was slight return of power. Here, then, was a probably irregular subacute myelitis, chiefly located in the dorsal spine. It had been diagnosed at home as tabes.

Profiting by the teachings of Russell Reynolds, a clever English physician, whose work in the seventies, as the result of an illogic reverence for all that is German in medical literature, has been almost forgotten, I have for years used, and with encouraging success, the bichlorid of mercury, either in small doses by the mouth or by inunction by means of some readily absorbable agent, and this has acted better than any other mercurial salt except perhaps the protoiodid. By inunction it is superior to any of the oleates or better-known salves or emulsions. Nitrate of silver or other drugs of the kind are, of course, useless and obsolete.

The treatment of special symptoms is, I am convinced, of great importance, and most encouraging results are possible, so that we should direct our attention to the modification of the pains, the ataxia and the cystitis which is so important a feature.

The treatment of pain is often most difficult, and a long list of remedies of more or less popularity have been utilized, often with little or no success. Pyramidon is about the best of the coal-tar remedies, but none of them is of much use except in dangerous doses when the pains are severe or of long standing. A careful record and study of nearly every case will show that the barometric changes have much to do with the pains, and it is for this reason that they are often called rheumatic. If this influence can be determined large doses of one of the salicylates or of aspirin may be recommended. The most effectual remedy, of course, is morphin, and it is my experience that if it is used under a physician's direction there is very little danger of producing a habit. Prolonged warm baths will often diminish the pain without any other treatment, and if proper apparatus is available a more extended kind of hydrotherapy may be prescribed. Gastric crises are often associated with intestinal disturbance and sometimes with autotoxis. Dietetic regulation should, therefore, be instituted, as well as the administration of antiseptics, especially hexamethylenamin, or borax. The crises of pain occasionally yield to the analgesics just suggested, as well as to the nitroglycerin in frequently repeated small doses. We may at the same time apply the actual cautery, or cup the dorsal region.

Several forms of systematic exercise have been recommended for the ataxia, that of Fraenkel being perhaps the best. The idea is to train the individual so that he may be able better to coordinate, thus overcoming the ataxia. Directions for the use of this series of exercises may be found in several of the standard textbooks; others will suggest themselves to the practitioner, who should study the necessities of each case and the details of the disorderly movements. I have been in the habit of utilizing a modification of the "setting-up" military drill. It is also well to encourage the patient to stand with his eyes closed, and this static ataxia may be modified by making the patient stand with his feet approximated with his eyes shut; the hand of the operator may be placed on one shoulder of the patient, thus supporting him, but it should be gradually removed so that, if possible, he may be made to preserve the erect posture without assistance. Sometimes this does a great deal of good and favors the development of that kind of courage and self-reliance, the loss of which causes so much demoralization when the patient is suddenly startled or he attempts to cross a crowded street.

As a rule, the persistent employment of regular exercise which teaches the patient to train his power of balancing and the direct corrective use of vision and touch, as well as precision in consuming particular acts, do much good, although the fact must be borne in mind that the real purpose is not to accomplish the effects of ordinary gymnastic exercise or violent massage. Of all diseases of the spinal cord none is more influenced than this by the evil effects of fatigue, so that indiscriminate calisthenics or immoderate walking are extremely pernicious and retard or actually thwart all our best-directed efforts. As a rule, it is best to advise long periods of rest and suggest moderate superficial massage, only sufficient to keep up the local tonus of the muscles or to facilitate the emptying of the capillary vessels.

Systematic exercise should not be used in cases in which there is much pain or in which there are gastric crises, or where there is reason to believe that the bones are friable.

In many cases the ataxia proceeds directly from the plantar anesthesia, which is usually most pronounced on the peroneal aspect of the foot.

Many suggestions have been made as to how this should be treated. Strange to say, it is not always profound nor is it of necessity persistent, although the rule is that it is a permanent sensory disturbance. Mere rubbing or faradization with a wire brush is rarely effective, and it is surprising sometimes how much the walk will improve if the high-frequency current be applied directly to the soles by means of a spark electrode. I have no faith in the use of electricity in any of its forms in any other way, although I have used them all. In hysterical cases in which there is a great suggestibility, of course this as well as any measures that appeal to the imagination will do temporary good.

In about 60 per cent. of cases of tabes there is more or less involvement of the bladder, which varies from mere dysuria due to atony, to paresis and dribbling, and actual cystitis produced by the accumulation of residuary urine is common. It is strange how much mischief such a condition with its attendant toxemia may produce. For some reason which we do not understand, the tabetic patient is especially subject to the influence of toxins and septic poisoning, while intestinal troubles as well as cystitis are responsible for a decided aggravation of his disorder and profound exhaustion, and a continued condition of this kind was at a previous time often mistaken for secondary tuberculosis.

About six years ago a patient came to me from a Western city. He was almost helpless and his ataxia was so pronounced that he had to be helped from his carriage and almost carried into my office. Beside the familiar disappearance of the deep reflexes he was exceedingly emaciated and feeble, and suffered from gastric crises with diarrhea and had the classic pains and ocular symptoms and a great deal of vesical disturbance.

His home physician had inserted metal sounds insulated to their tips, and applied galvanic current to the interior of the bladder, but no attempt had been made to wash this viscus, although it contained at all times much offensive urine. Two days after his arrival in New York he took to his bed, having rigors and high temperature and other evidences of infection. His temperature ranged from 101 to 105, and for several days it was between 103 and the latter figure.

His condition became so alarming that his friends were sent for. Ordinary lavage of the bladder promptly removed the difficulty. The patient's temperature subsided, and in a week or so he was permitted to leave his bed. Then the use of systematic daily washing and catheterization and the internal administration of hexamethylenamin and atropin effected a remarkable change. Under proper regimen and supportive treatment the patient soon became able to walk, discarding the help of other people and his cane; got in and out of his automobile, and now has very little ataxia or other symptoms, and actually plays golf.

While the patient's reflexes are still absent, his affection seems to be at a standstill, and he is much encouraged. In these cases, which are numerous, it is of importance to wash out the bladder at regular intervals for a long time, and this may be done with a normal salt solution or a borax solution, while hexamethylenamin may be given well diluted in ten-grain doses, and especially when it becomes necessary to discontinue the lavage for a few days.

In this connection I may say that I never have seen a case of tabes in which there were any urethral lesions.

As a claim has recently been made that the determining cause of tabes is a lesion of the urethra, I wrote to Dr. James Pedersen, one of the most skilful genitourinary surgeons and urethroscopists, who replies: "I am willing to say that I do not recollect having treated with benefit to the general condition any true case of locomotor ataxia. I can, however, say that cases with symptoms of spinal and cerebral neurasthenia, having at the same time genitourinary lesions, have, of course, been benefited by local treatment."

These patients require a warm winter climate and at all times one that is preferably dry. San Antonio is an excellent place, and Lower California is also suggested, provided that high altitudes are not sought or do not increase the patient's distress. There are various places in Colorado well adapted for the sojourn of tabetics.

It must not be forgotten that a considerable number of patients, specially in cases due to shock, trauma or hysteria, in which there is no syphilitic basis, may be cured in a comparatively short time and by very simple measures. I have elsewhere recorded a very interesting case of this kind, and since its publication I have had equal success with others.[1]

CURATIVE EFFECT OF REST IN CHILDREN WITH PERSISTENT LOSS OF APPETITE.[*]

IRVING M. SNOW, M.D.
Clinical Professor of Diseases of Children, University of Buffalo.
BUFFALO.

There is occasionally seen in children a group of symptoms which are benefited by rest, and by no other treatment.

The little patient, from 2 to 10 years old, is brought to the physician with a general complaint that he has been in poor condition for several months, or that for a long time he has been alternately up and down, going to school for a few weeks and then collapsing into a curious state of physical prostration. There is usually no history of antecedent illness or predisposing cause. The parents will state that the child has a most uncertain appetite, and, in fact, at times will eat so little that it is a wonder that he can exist. Often the patient will refuse several meals in succession and will habitually reject the most important articles of diet—meat, eggs, vegetables. Often the boy or girl is subject to the most correct regimen; the meals are nicely prepared, most appetizing in variety and flavor, appealing to any normal childish palate, but the child remains absolutely indifferent to his food, taking the most minute quantities after prolonged urging. As a consequence of this voluntary semi-starvation, the chronic lack of appetite is associated with excessive muscular weakness and certain nervous symptoms. The child shows a singular unrest, is unable to keep still, but tires under the least exertion. He can not run or walk any distance without fatigue.

A boy of this type will show no physical courage. All normal boys are combative, a little inclined to play the bully, eager to show their strength and skill. Pluck is a valuable asset for a boy. It is well for him to fight occasionally for his rights; it increases his self-respect and prevents much of that hateful nagging which is universal in school life.

The boy's parents and friends are secretly ashamed of his lack of nerve. A girl shows equally her feebleness by her languid movements and has to be urged to take exercise. For several months there may have been a steady loss of strength or recurring periods of prostration.

If under 5 years of age, the child may behave differently. Part of the time he is running about, fussing with his toys; in active motion for a few minutes, then lying down or wanting to be held. He is either in incessant motion or limp with fatigue. There is no rest for the child's attendant. He is capricious and ill-tempered; will not eat, play or sleep at the right time.

In temperament, such children may be of an attractive type, animated and graceful in manner, charming in expression and talk, but nervous and precocious. More often they are irritable, emotional, highly neurotic; at school they learn with difficulty, have small powers of concentration, are easily confused, and are much worried over the more rapid advance of their comrades. They are poor sleepers; if very young, will not take a noon nap; if older, do not fall asleep early in the evening—toss about in bed, awake, languid, unrefreshed.

There may be the history of an imperfect convalescence from an infectious disease, or a steady deterioration in physique without adequate apparent cause. Sometimes the parents will say that the child has had persistent treatment in the way of tonics, country or sea air, well-regulated gymnastics, with temporary benefit or utter failure, the child coming home a complete wreck from a long vacation. He has perhaps grown rapidly in height without any increase in weight, which is stationary or even diminished.

SYMPTOM-COMPLEX.

The patient should be carefully examined and every detail of his life considered. In the etiology of the malady, heredity generally plays a minor rôle. The parents are as likely to be of vigorous physique as of delicate, neurotic constitution. All local or constitutional diseases should be searched for as a cause for the patient's continued ill health. He or she will be found to be under weight with slender limbs and poorly developed muscles; pale and rather withered in appearance. The tongue will be clean, with no serious disturbance of digestion, no secretory or motor gastric lesion. There is a general constipation from inanition. The pulse may be rapid, irregular or often normal.

Particular attention should be given to the condition of the heart. The cardiac symptoms will often be interpreted by the personal equation of the physician's mind. A considerable cardiac dilatation may exist. The heart sounds may be normal or so-called functional murmurs heard at the apex or pulmonic areas. As a rule, the heart is in good condition and all organs and functions are in order.

---

[1] Railway and Other Injuries, etc., p. 209 et seq. New York, 1904, William Wood & Co.

[*] Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Thus the positive symptoms in our symptom-complex are:

1. *Chronic Loss of Appetite.*—Patient under weight; indifferent to food.
2. *Extreme Weakness.*—Inability to run, walk or play; patient collapsed with fatigue at frequent intervals during the day.
3. *Nervous Disturbances.*—Deficient, restless sleep; lack of concentration at study. Some cases emotional and irritable; others apathetic. Child very fidgety in manner, illustrating the pathological law that deficient capacity for functional activity is associated with undue readiness for slight actions.

The condition under discussion is to be clearly distinguished from anorexia nervosa, first described by Sir William Gull, and recently ably reviewed by Forchheimer in an article, "Anorexia Nervosa in Children."

Playfair states that true anorexia nervosa is a very rare neurosis, a psychosis characterized by an aversion, an excessive disgust for food, indicating profound alteration in the nervous system.

Anorexia nervosa is a type of hysteria causing a rapid loss in weight without organic lesions. It is accompanied by delusions and by marked hysterical manifestations. The patient shows a strange unrest and tendency to overfatigue from constant walking, which leads to the exhaustion so easily produced in the starved body. The essential point, when dealing with anorexia nervosa, is to remove the patient from his domestic surroundings and to associate isolation with rest, massage and overfeeding. All authors agree that without isolation the treatment will certainly fail.

This article deals with a persistent loss of appetite or indifference to food, from nervous or muscular exhaustion, with no cerebral disturbance. The patient may be emotional, petulant, naughty, but there are no delusions, no hysteria. In both conditions there is a constant unrest and tendency to walk to the point of exhaustion, resulting in prostration and rapid emaciation.

The physician is apt to concentrate his attention on the anemia or cardiac dilatation, or to regard the child's nervousness and lack of appetite as the malady itself and not due to the underlying cause, a deficient power of muscle and nerve to sustain any prolonged effort.

Slight temporary cardiac dilatation is common enough in children and may produce weakness and anorexia, but the symptom-complex under discussion may also coexist with a heart of normal sounds and size.

The influence of school life in depressing the health of children is very much overrated. Sometimes the hygienic influences at home are at fault; generally the patient is not fit to go to school at all; any exertion, physical or mental, produces a deterioration in physique.

The patient's ill health is often perpetuated by the false idea that exercise and out-of-door life are beneficial. It will be found that whatever the child does is too much for his strength. Often the patient's extreme nervousness stimulates him to be in constant motion, to run about and play for a few minutes, and stop from exhaustion, a state analogous to the nervous gestures and lack of repose of a neurotic man or woman. Gymnastics increase the trouble; the most skilfully administered tonics—iron, arsenic, strychnin, etc.—produce no permanent improvement.

The case being thoroughly reviewed, and definite organic lesions being excluded, it will be evident that the underlying cause of the chronic exhaustion and anorexia is either a congenital lack of vigor, or is the result of faulty environment and habits and mode of living.

Such conditions occur in all stations of life, but are most frequent in children of a nervous type, whose interest in life is most intense, who may dominate the family by their strong will and persistent selfishness.

If the semi-invalidism and anorexia are merely due to too much milk, too monotonous a diet, to an imperfect convalescence with an insufficient period of rest and treatment, or too vigorous athletics, a change of regimen will insure a rapid and permanent restoration to health. But there are some children who early show an inherent weakness of constitution, a nervous excitability which may be a formidable handicap to their future career. Both in childhood and in maturity, after an unusual strain, they sink into a state of physical and intellectual prostration. If the constitution is correctly understood, they are quickly restored again.

TREATMENT.

I have adopted a plan of treatment in this chronic anorexia and prostration which may not be original, possibly is centuries old, but which is certainly effective, though strangely neglected. The idea is to give the patient a more or less prolonged period of inactivity, to allow him to rest until his reserve forces are accumulated. The inherent vigor of the patient is given opportunity to recruit. The parents are told that the cause of the child's ill health, poor appetite, insufficient sleep, ill temper, lack of muscular endurance, is chronic exhaustion, and that the boy or girl will probably improve if kept in bed two or three weeks and then given a short day of perfect freedom.

This advice will at first seem heroic; the mother demurs at the incessant care and attention which the child, if young and self-willed, will require. A good nurse is a valuable adjunct, always assuming her to be of a good temper, agreeable disposition and able to control and divert the little invalid.

The directions are that the boy or girl be put to bed and kept there for two weeks. In winter the patient, well wrapped up, may be given an airing with the windows open. In the summer the child may be put in a hammock or may lie on a lounge out of doors. A younger child may be placed in a perambulator, but no driving or automobiling, which excite and tire the patient and may offset the good of the enforced confinement, is permitted. The body should be sponged off and well rubbed, morning and evening, as a matter of toilet, and also to relieve the restlessness. A suitable, nutritious diet, well cooked, varied and attractive, with no especial restrictions should be served.

The child's attendant may amuse him with games and toys or read diverting stories, but may never scold or irritate it. Tonics may, of course, be given, but they are accessory, not essential elements of treatment.

EFFECTS OF THE REST.

The youngster will at first rebel at the irksome restraint and interference with his wishes and will cry and fret to get up. In three or four days the patient will grow more tranquil, realizing that his will is not the law of the household, and will commonly make less trouble in bed than when he was fussing about the house. He is no longer incited to study, to play or to compete with other children. In the absence of fatigue and nervous strain the child turns to eating and sleeping. After a few days in bed, the effects of rest will be evident in the appetite. The child will show a keen and critical interest in his meals, consuming enormous portions. The food is perfectly digested. As the constipation in the case is due to underfeeding and lack of muscular tone, no laxative is now necessary. Sleep will come quickly in the evening—quiet, continuous, refreshing slumber.

The fine appetite of convalescence from an acute disease is due partly to the cry of the tissues for nourishment to restore the wasted cells, but also to the maintenance of muscular inactivity. The nervous secretory mechanism of digestion is not inhibited by fatigue or exercise past the power of endurance.

Less food is required in conditions of rest than of activity, but it is a clinical fact that the way to make a tired, growing child or an overworked, neurotic adult eat is to make him take rest. There is less difficulty in fattening an emaciated patient in bed than when he is up and about. Sleep intensifies the value of rest, insuring more absolute relaxation. The exact length of the stay in bed depends naturally on the previous condition and the response to treatment.

Rest should be continued until there has been a considerable gain in weight, a good appetite and natural sleep for ten or twelve days. There will now be a return of muscular vigor with a repose of manner as contrasted in the jerky, twitchy actions before commencing treatment.

An average period for the treatment of complete inactivity would be about two weeks. The nutrition, strength and appetite being satisfactory, the child may be dressed and given an hour's perfect freedom, out of doors if preferred. Improvement continuing, the period of activity may be progressively increased one hour more daily every three or four days until the child has six hours' perfect freedom in the middle of the day, out of doors for a part of the time. If the child be still delicate, or if the health be not quite at a normal standard, the short day should be continued for several months.

At this phase in the treatment, nutrition is much stimulated by a change of air, country or seashore, the patient being properly restricted in violent athletics and trials of strength. It will now be found that the powers of endurance of both muscular and nervous system are permanently augmented, that there is natural sleep, a steady increase in weight and a ravenous appetite with perfect digestion.

Most noticeable is the change in the disposition and character of the patient; the physical effect of the discipline and long tranquility result in the disappearance of the child's petulance and disobedience.

The boy or girl will develop good powers of mental concentration in study and conversation. The child will have spirit enough to play or walk or run for the relatively short time for which freedom is allowed. When the case is again medically reviewed, the cardiac dilation will have disappeared, the anemia will have been cured.

After a period of from two to four months, restraint is no longer necessary; the child may live its normal life. A recurrence of the anorexia is unlikely. The child will have grown in height and weight, is practically presented with an improved constitution. Some children have a large capital of strength, then others can bear only a few hours of activity, a minimum of mental strain. Their capacity should be estimated by their parents and physician, and their habits and career arranged accordingly.

It will at once occur to the reader that not all children with poor appetites require weeks of rest in bed. True; there are numerous borderline conditions in which two or three days of inactivity or a midday rest will suffice; but in these cases the languor or nervousness and anorexia are of short duration. If the symptoms have lasted for several months, the short or partial rest-cure is a waste of time; the invalidism will presently recur. To obtain a good result the full details of the treatment just described will have to be carried out.

If these patients are untreated, what becomes of them? The final result is apt to be a chronic delicacy of constitution, a lack of endurance, a fragile physique which will tell in after life. Still, adolescence brings new strength and varied interests and the majority of children struggle into a fair constitution in adult life.

ILLUSTRATIVE CASE.

Patient.—Girl, aged 5, only child. Complaint, lack of appetite and progressive emaciation.

History.—The patient has eaten almost nothing for two weeks; is absolutely indifferent to her food. She was born after a normal labor; was nursed three months; was afterward fed on cow's milk. She had occasional attacks of indigestion (vomiting), lasting a day or two, but had had no infectious diseases. During July she played with a cousin three years older. The incessant activity necessary to keep up with a stronger child produced the final collapse.

Examination.—Child of an active, nervous temperament; was always in motion; had no noon-day rest; was constipated; was a withered-looking child; weight, 28 pounds. Average weight at 5 years, 39 pounds; had lost 7 pounds in one year. Physical examination was negative.

Treatment.—The little girl was put to bed for one week. The second week she was allowed to lie in a cot out of doors. She proved most amiable and amenable to treatment. After the second day in bed she began to eat ordinary diet. In the first week she gained 3 pounds; in the second week, 1 pound. She was then taken into the country and given from one to two hours a day perfect freedom on her feet. Four months later I saw her again. She was plump and rosy, with a good appetite and regular stools. She now has from five to six hours daily of freedom to run and play. Her present weight is 34¾ pounds, a gain of 6¾ pounds in four months.

476 Hamilton Street.

ABSTRACT OF DISCUSSION.

Dr. Arthur W. Fairbanks, Boston: I have been preaching of the advantages of rest in the diseases of childhood for a number of years; and at Atlantic City a year ago I put forth one more plea for its more general employment. I believe that nervous energy, the nervous impulse to expenditure of muscular exertion in excessive amount by children is out of all proportion to their ability to respond without damage to the organism. He who will use his eyes will find confirmation of this fact on every side. I believe that the chief deleterious effect of this extravagant expenditure of muscular energy is felt by the heart, as part of the muscular system, but by far the most important part. I was interested to hear Dr. Snow say that dilatation of the heart is an occasional feature of these cases. He says that such children are unable to run, walk or play. That was exactly the condition in a series of cases that I studied. I have termed these subjective and objective disturbances in heart function, an "essential insufficiency of the heart," which, in its effects, is of infinitely more serious consequence than insufficiency of the muscles elsewhere. In my paper last year, of which this was the title, I described cases identical with those mentioned by Dr. Snow, cases I have observed during eight or ten years. If one will question these children he will find subjective complaint suggestive of insufficient heart as well as objective evidence of the same. I have always maintained that the diseases and accidents of childhood, when they do not result in permanent ill effects, are really often blessings in disguise, for they enable the child to get the rest that he would not otherwise receive. Many times parents will say, after a child has had an attack of measles, or some other slight illness, that the child is better than it ever was before. I do not think that the period of rest advocated by Dr. Snow is long enough. With a two weeks' rest, it would be only a question of time when the symptoms would recur, if in fact all of them disappear in so short a time. I also advocate the use of massage and warm saline baths. Later I use exercises, such as are employed in cardiac diseases. This entails careful nursing, but it is perfectly feasible to carry this out in any case at home, and all the results Dr. Snow has mentioned will follow if the case is treated in that way. The mistake is too often made by the family physician of not paying sufficient attention to conditions that do not present a picture described in his text-books.

Dr. Samuel J. Walker, Chicago: Dr. Snow has outlined much of the course of treatment I carry out in many of my own cases. I think that we can not emphasize too much the value of rest in the chronic loss of weight and of appetite and in all of the conditions below par. Dr. Kerley read a paper on malnutrition at Atlantic City that also made a marked impression on me, as it advocated the extreme value of rest in these cases not only in chronic loss of appetite but in all cases in which the child is below par. Where you suspect tuberculosis and can not get anything positive in the way of physical signs, what do you do? If the child is petulant, irritable, has a little rise of temperature in the afternoon, is losing in weight perhaps, what is the treatment? Rest, fresh air, hygiene, etc., all that Dr. Snow has brought out. Or take another class of cases. In many cases, weeks before the development of the typical choreic condition, there is this irritability, restlessness, and so forth, that precedes the development of the condition. Under such a method of rest as Dr. Snow has described the child's condition could be so improved that chorea would not develop.

Dr. Charles Douglas, Detroit: The cases reported here to-day give the impression that we should apply this method in a great many conditions other than the ones immediately presented to us. There is no doubt of the beneficial effects of this form of treatment. If we would look further into the physiologic processes going on we should be able to apply this method in other conditions as well as those mentioned. There can be no doubt that these children are overtaxing their strength just as a nursing mother often does when laboring too much. Enforced rest allows the nutrition to be appropriated, thus strengthening the digestive glands. The child is thus enabled to digest a larger amount of food and we see the benefit in a general improvement.

Dr. T. D. Parke, Birmingham, Ala.: Within the last few months I have seen proof of Dr. Snow's theory in a child showing the condition spoken of. The child had been spoiled and was under a nurse, who had absolutely no control over it. I insisted on the employment of a trained nurse. The child was kept in bed two or three weeks with all the windows open. Its appetite soon returned, as no effort was made to coax it, and after that there was steady improvement in weight and general condition. Anyone who attended the scientific exhibit at Atlantic City and saw a demonstration there, will never again question the desirability of keeping the muscle of the heart in good condition. The experimenter had a reservoir of water connected with a tube that communicated with the left ventricle through the aortic orifice. As the reservoir was raised, the water flowing into the ventricle under pressure, mechanically closed the mitral valve. When the reservoir was lowered the resiliency of the heart wall forced out the excess of water into the tube and the valve opened, thus giving a beautiful illustration of diastole and systole. The same experiment can be repeated through the pulmonary orifice for the right ventricle. These children are apt to have weak muscles generally. Wherever we find the muscle generally weak we must expect the heart muscle to be weak; and when the musculature of the heart becomes weak and too much strain is put on it, dilatation is apt to result. We should bear this in mind whenever a child has undergone a prolonged exhausting illness.

Dr. C. G. Kerley, New York: One year ago, as Dr. Walker remarked, I read a paper along similar lines and advocated a modified rest-cure. I still think that that is far better than the scheme advanced by Dr. Snow. I fail to see why a child who has simply a loss of appetite should be kept in bed. I get better results, I am sure, by having the child take his breakfast in bed. He is allowed to get up at 10 o'clock and remain until 12 o'clock. Then he has dinner and rests until 2 or 2:30 p. m. He is then allowed to be up for two or three hours in the afternoon. I believe that Dr. Snow would get better results by giving the child a change of air and a change of scene than he does by keeping the patient constantly in bed without any variety in his life. The whole matter is simply a question of the conservation of vitality. Most children overdo physically, particularly when playing with other children. They overdraw on their bank account of vitality and the result is a loss of appetite and all the other changes that go with an excessive expenditure of energy.

Dr. C. Rutherford, Chicago: I desire to call attention to the value of prolonged rest and enforced feeding in incipient tuberculosis. Last year in a case of tuberculosis of the hip-joint, by rest and forced feeding most excellent results were obtained.

Dr. Irving M. Snow, Buffalo: I agree with Dr. Fairbanks especially that the period of rest should be prolonged in cases of dilatation of heart. But in the paper I presented to-day I was not speaking of that. It is a fact, too, that what one considers a dilatation of the heart is dependent somewhat on the physician's idea of where the apex should be. Dr. Fairbanks thinks that the period of rest is too short; Dr. Kerley thinks that it is too long; but I have found that by keeping children entirely at rest for two weeks we can keep up the progressive gain in weight. I do not think that the time of rest in bed mentioned by Dr. Kerley is enough. I think the child should be kept in bed a fair number of days. The child is simply left alone; in this paper I do not advocate forced feeding.

HYPERPYREXIA IN CHILDREN.

ITS CAUSE AND TREATMENT.*

PHILIP MARVEL, M.D.
ATLANTIC CITY, N. J.

Pyrexia is one of the most complex of all symptoms of disease and one of the symptoms most constantly present in pathogenic disturbances of metabolism. It is rarely absent in acute infections or in severe trauma, and more frequently characterizes the nature of the disease and the severity of the trauma than any other symptom, except the rashes peculiar to certain contagious diseases.

Despite the many difficulties and indeterminable problems met in the study of the various causes of fever and the complexity of its maintenance, a large number of investigators have assiduously pursued series of researches, with the result that, as yet, science is without an altogether satisfactory solution of the subject. In the light of our present view of the fundamental causes of fever, so far as they are known, a brief retrospect of the past half century would seem both permissible and interesting from the standpoint of contrasting the theories and hypotheses of the past with the more recent discoveries of micro-organisms, their influence on metabolism and as primary causes of disease, particularly if we are now to consider pyrexia, in infectious diseases, as "a response, in the metabolism, to the invasion of micro-organisms, and toxic disturbances of the nervous regulation of temperature."

As far back as the middle of the nineteenth century the subject of pyrexia was one of great interest to those who had caught something of the inspiration of Johannes Müller's teachings, among whom there was none more earnest and capable than the beloved and venerated Virchow, who, having given a great amount of thought and much personal attention to the detailed investigation of the subject, was greatly interested in the hypothesis which described fever to be a "reflex process," in which the phenomena were responses to stimulation of the spinal cord by means of the "organic nerves."

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Contemporaneous with Virchow, but holding an altogether different view of the subject, were Weber and Schiff; the former, having recently discovered the inhibitory nerve of the heart, suggested that the central nervous system governed the circulation through two antagonistic forces influencing the heart, the one exciting, the other quieting, the cardiac action; and the latter, claiming to have discovered the "vasomotor system of special nerves," supposed this system to control the tone and activity of the capillary vascular system.

Shortly after Schiff's declaration, Virchow, who had already caught something of the idea of "antagonistic circulatory" forces, that is, the idea that fever might be a neurosis, expressed himself accordingly in his Treatise on Pathology, published in 1853. He was the first to teach a broader and more comprehensive view of the cause of pyrexia, which he afterward showed was not a mere production of heat, overaction of the heart or disturbed tension of the vascular system, but an actual failure of proper nervous control, and a disturbance, rather than an overproduction of the normal forces.

However, contributory science was too immature and imperfectly worked out, at that time, to furnish proof of how control was exercised. It, therefore, remained for Virchow to suggest a system of "moderating centers," which could influence not only the heart and blood vessels, but also the great complex organization of forces which is now designated metabolism. He believed fever to be a condition resulting from the state in which the nerves had, for some indefinable reason, lost their control over the "organic processes," which assumption was probably the first intimation of the part which metabolism is believed to play in the rôle of pyrexia.

In 1855 Traube discovered that in pyrexia the elements of nitrogen were increased, and this gave rise to the declaration that, if fever be a neurosis, then there must be a system of "trophic nerves," by which the chemical processes of the organisms were controlled; otherwise, the disturbances of the nervous system could not include tissue degeneration. Therefore he, as well as Virchow, held that there must be a "fever-producing agent," but differing, not with respect to its action on the inhibitory but on the vasomotor nerves, resulting in a contraction of the peripheral vessels, occasioning a diminution in their volume of blood, and, in consequence, the quantity of heat in the surface of the body, coincident with the rise of internal temperature. The increase in the difference between the degree of "normal external and normal internal temperatures, he considered to be fever, and its decline or defervescence due to nothing more or less than a cessation of the vasomotor spasm."

However, the explanation was short-lived and accepted only by a comparatively small number, and by them but a short time, for Liebermeister had already begun his investigations of the subject with the aid of the calorimeter, the outcome of which was to demonstrate that when the surface loss of temperature was entirely annulled, by raising the external temperature of the body to a point where no heat was parted with, the increase of internal temperature was nothing like so rapid or high as in the initial stage of many febrile states; therefore he formulated the well-known theory which bears his name, viz., "that in fever, as in health, constancy of temperature is insured by the adaptation of production to discharge and not of discharge to production," and, secondly, that "in fever bodily temperature is recorded in the same way as in health, with this difference, that the "norma' has become several degrees higher."

This theory was considered far from satisfactory by many, and not without serious objections, because, first, experiments and clinical observation failed to prove the statement that arrest of surface rise of temperature was adequate to produce pyrexia; and, second, the declaration that febrile temperatures tend to reach their "norma" at several degrees higher than normal, was open to critical difference of opinion.

About this time, Senator, one of the most thorough and capable investigators of his day, impressed by the variance of the theories which had preceded his conclusions on the subject, took up the study and arrived at results differing somewhat from those of Traube and Liebermeister, who differed slightly in their beliefs from Virchow, particularly with respect to pyrexia being a disturbance of the nervous system by which the constancy of the bodily temperature was maintained. It remained for Senator to present a still broader, if not a wholly different view of the subject, in which he recognized both the vascular and thermal disturbances and also the metabolic phenomena. Hence, for the first time, special changes in the metabolism were made a fundamental cause of pyrexia.

Simultaneous with Senator's investigations[1] were those of Leyden, whose conclusions differed from Senator's more with respect to the fact that the latter claimed to have found no marked increase of respiratory discharge of water or carbon dioxid in animals and, therefore, concluded that the only essential metabolic change in pyrexia related to increased degenerative changes in proteids, but the former, having extended his investigations to the study of the subject in man as well as in animals, and having estimated the loss of heat in limited portions of the body by the aid of a cylindrical calorimeter, calculated the relative loss from the special surfaces exposed with that from the whole surface of the body and inferred that, in fever, even where there is no visible perspiration, thermolysis might be even 40 per cent. greater than in health, and, contrary to the findings of Leyden, noted a corresponding increase in the respiratory discharge of both water and carbon dioxid, which he attributed to increased nervous activity and coincident respiratory movements.

Pflüger, a distinguished physiologist of his day also became actively interested in the study of this subject, directing his experiments more especially to determining the intake of oxygen and the output of carbon dioxid in both normal and fevered animals, with results that inclined him more particularly to the view of Liebermeister, viz., that "normal regulation consists in the adaptation of production to discharge," and that increased production is the essential element of fever.

This announcement, with further investigations by Senator, caused a modification of his former hypothesis.

---

[1] Researches on the Processes of Fever, 1873.

which he subsequently stated as follows: "There is no absolute nor arbitrary interdependence of the disorder of nutrition and the pyrexia which follows; the only fixed causal relation being that which exists between the pyrexia and the coincident disorder of the cutaneous circulation."

Even this simple and apparently comprehensive explanation of the cause of fever was not permitted to go unquestioned for any length of time, for shortly thereafter Cohnheim, after a critical review of the subject,[2] gives decided preference to the theory of a neurosis, and, in a carefully arranged summary, declares as follows: "The nervous system presides over the thermogenesis no less directly than over the thermolysis," thus favoring the view of increased heat production throughout the febrile processes, while he admits that the cutaneous circulation is restricted in the initial stage of fever when the rise of temperature is rapid, but does not accept the declaration that this is the cause of the rise. Moreover, he believes the remarkable feat of the diurnal range and variations in pyrexia, which are so much greater than in health, are due to thermogenesis rather than to special changes in the circulation.

To appreciate properly the deductions resulting from the earlier investigations, it must be kept well in mind that up to this date, a little more than a quarter of a century ago, little or nothing was known of the cause of either periodic or bacterial fevers; hence there could be no reason at that time for attributing any direct relation between the circulatory activity, the presence of micro-organisms and the height of the fever succeeding their invasion. To Koch, Pasteur, Metchnikoff, Behring, Pfeiffer, Roux, Ehrlich and many other pathologists and bacteriologists humanity owes a debt never to be discharged, for their remarkable discoveries in the bacterial world and for the knowledge obtained of specific toxins and toxic substances.

It is true one can scarce conceive of either pyrexia or hyperpyrexia without giving great consideration to the master tissue of the body, viz., the central nervous system, and its far-reaching influence on the intercellular forces and major systems of circulating fluids, for under certain protected conditions microorganisms have little or no effect on the organized forces of the body; hence no hypothesis admitting an explanation of the causes of pyrexia or hyperpyrexia could be declared or even considered, that omitted a proper consideration of the relations existing between the central and peripheral nervous and circulatory systems, disturbance of these being the chief adjunct causes of fever. Indeed, any definition of fever which omitted reference to the associated influences of either increased or diminished activity or partial paresis of the central and peripheral nervous systems or of the circulating fluids of the general economy, would be most incomplete for the reason that extremely high temperatures in the febrile states are as often observed in traumatic injuries and in severe and prolonged exposure to both artificial and natural heat and also to the external action of cauterizing chemicals and internal ingestion of drugs as in acute pathogenic diseases.

Certainly, when clinically studied, one finds the average pyrexia so closely resembling the symptomatology and laboratory findings observed in the few infections in which the micro-organisms have been isolated, that we may safely assume that, in the majority, and I feel like saying in all, of the cases of infection, the micro-organism is the primary cause of the pyrexia, and where hyperpyrexia is associated therewith, the causes are the same, with the addition of some yet unknown interference with heat production and its deflection and that, through the circulatory and nervous systems, secondary causes are made more operative.

In the cases of extremely high temperature following the ingestion of poisonous drugs, of sera, of chemical irritants or exposure to intense artificial or natural heat, it would seem proper to classify these cases not as pyrexias or hyperpyrexias, but as high temperatures arising from varied causes which are even less well understood than those occasioned by micro-organisms, and might better be classed as hyperthermias.

In traumatic injuries, whether the injury be external or internal, direct or indirect, whether within the central nervous system or of some other tissues of the body, occasioning a structural lesion, the excitement causing the pyrexia would be, undoubtedly, primarily some external force.

For convenience of discussion I have divided the extreme temperatures into four classes, viz.: (a) Those due to micro-organisms and, occasionally, parasites; (b) those due to drug poisons and chemical cauterizations; (c) those due to traumatic injuries, and (d) those due to psychic and other neurotic disturbances. I appreciate the fact that in the foregoing division there may properly arise a question as to the propriety of such a classification, but since the same is made for the convenience of this discussion rather than with reference to scientific acumen, doubtless the above divisional arrangement will be privileged. For obvious reasons I deem it proper to confine the further discussion of this subject to class (a), in which the causes of pyrexia and hyperpyrexia are accredited to micro-organisms. That the variations in temperature are due to some substances pathologic, chemical, toxic or ptomainic—produced by the specific microbe characterizing the disease present—I assume will be accepted without further reference or special proof.

For convenience and a clearer understanding I shall consider the subject of infections further under two subdivisions, viz: (1) Those produced by endogenous and (2) those by exogenous causes.

By the term simple toxemia or ptomaine infection, I would characterize that condition following an overloading of the blood and lymphatic circulation with normal or abnormal food, or with tissue metabolism, as a toxemia arising from endogenous causes, and all cases of pyrexia arising from causes thus introduced into the circulations as endogenous diseases. All diseases which are sharply separated from those arising from food and tissue metabolisms and are of bacteriologic or pathologico-chemical origin, are more particularly known as contagious infections, which are truly toxic pyrexias, as arising from exogenous causes.

It is possible that the former may be bacterial in origin, but the micro-organisms involved are usually habitants of the intestinal tract and should be considered as differing and wholly apart from those present in acute toxic and contagious febrile states. The latter, in which bacterial wastes are elaborated from the activity of the organisms within the various tissues of the body, especially in the more important viscera, causing intense intoxication and poisoning of the system at times sufficient to threaten and even destroy life, differ greatly from the former and should be so recognized.

---

[2] General Pathology, II.

Each of these infections produces its own specific product, the direct or immediate influence of which depends on the resistance within the system, by the presence and activity of the various so-called antibodies—anti-agglutinins, antitoxins, opsonins, etc. To what extent these primary or fundamental causes are vegetable, animal, pathologic and chemical I will not attempt to state, but the following inference would seem quite probable and even permissible, viz.: That the degree of the pyrexia is, in all probability, due to the intensity of the infection and the inability of the body to resist the invasion though the height of the temperature may be influenced, to some extent, by the heat environment to which the individual is exposed, as it has been noted in the records that a much larger number of cases of hyperprexia occur in the months of June to September, inclusive.[3]

Before disposing of the question of the causes of pyrexia and hyperpyrexia, the subject of the ductless glands and the relation of their secretions to functional and organic disease through disturbed metabolism would seem worthy of consideration. Though much has been written on the subject, particularly on the influence and activity of the perverted or abnormal secretions of these glands on the nervous system and the more important glandular organs by a number of French writers, and perhaps no less by one of our own countrymen, Dr. Sajous,[4] their place as a causative factor is far from proved. With our limited knowledge of their function and relation to the major forces of the economy, we can only regard them as secondary in their causal relation.

There is to-day, as in the past, with respect to this subject, some tendency to fix the responsibility of least well-understood happenings on least well-known causes. Simple abstract inductions, though obtained by well-defined methods pursued by carefully detailed investigations, rewarded by concrete findings in the study of many of the problems presented in the diseased and abnormal human forces, are not to be accepted as proved facts, and, until we know more of the *vis a tergo* in the circulation; of the life element and function of the protoplasmic cell; of the component forces and intercellular chemistry of the glandular secretions, and of the mutual exchange between the three great systems and their inimitable relations, will we know most of all that enters into the phenomenon we designate fever. Because the word is a convenient clinical term, it nevertheless represents a group of phenomena having a more or less definite sequence and origin which we can best express as a condition produced by pathogenic organisms or their products, operating within the body, disturbing the economic forces and raising the temperature "norma" to abnormal heights, or a more or less certain response in the metabolism to the invasion of micro-organisms or toxic disturbances of the normally regulated temperature.

In the following briefly tabulated cases of hyperpyrexia, which have been studied in my practice, I shall refer only to those which had, associated with high temperature, *some special feature of interest other than* the pyrexia. Age limit was from eight months to thirteen years.

TABLE OF CASES OF HYPERPYREXIA IN CHILDREN.

No.	Diseases.	Temperature.	Number of cases.	Per cent. Cured.	Mortality.	Per cent. of diseases.
1.	Acute articular rheumatism	106	1	100	0	0
2.	Bronchopneumonia	106 106.6	9	45	5	55
3.	Cerebrospinal meningitis	106 108 8	2	0	2	100
4.	Erysipelas	106-106 4	3	100	0	0
5.	Enterocolitis, acute and chronic	106-107 2	6	50	3	50
6.	Measles	106-106.8	4	100	0	0
7.	Intestinal worms (Ascaris Lumbricoides)	106-106 8	2	50	1	50
8.	Pyemia	106-107	2	0	2	100
9.	Septicemia	106-106.6	1	100	0	0
10.	Scarlet fever	107	1	0	1	100
11.	Tonsillitis, follicular; one postpharyngeal abscess	106-106.4	6	83	1	100
12.	Tuberculosis (meningeal)	106 110	5	0	5	100
13.	Tuberculosis (pulmonalis)	106-107.2	2	0	0	100
14.	Variola	106.2	1	100	0	0
			45	Av. 48.8	22	

I will speak first of the cases of enterocolitis, of which there were two, one acute, the other chronic with acute exacerbations; the first is of interest from the circumstances which surround the rise in the temperature:

Case 1.—Bessie A., 17 months old, ill ten days, bottle-fed, cause of illness, milk infection. Previous to illness child was well nourished, quiet and easily cared for. The temperature had been ranging between 102 and 104 F.; the largest number of stools in previous twenty-four hours was fifteen, mucus, muco-purulent and slightly blood-stained.

Treatment consisted in the administration of calomel, castor-oil, bismuth and alkalies, assisted by colon irrigations; fed on dilute egg albumen and milk whey. Parents being *non-residents*, were anxious to return to their home and family physician. Child's temperature on leaving Atlantic City in the afternoon was 104.2; journey was made in an ordinary passenger coach, child remaining on a pillow, supported on nurse's lap: cold compresses were placed over forehead and upper part of the head and frequently renewed; time consumed in travel, four and one-half hours. Temperature *on arriving in* New York was 107.2.

Child was immediately immersed in a cold bath preceded by being wrapped in a blanket wet in warm water. "Tubs" were repeated at intervals of one, two and three hours until the temperature was reduced and remained between 102 and 104 F. The dorsum was also rubbed, in the interim, at frequent intervals, for three to five minutes, with *pieces of* ice held in a towel, protecting the child with hot water bags *along the* spine between the shoulders and at the feet; colonic lavage with cold water was also used. Because of the stasis in the extremities and the cyanotic state of the mucous membrane, the treatment used internally during the time of temperature reduction was nitrite of amyl inhalations and hypodermic injections of 10 minim doses of Hoffman's anodyne.

After vigorous treatment of between *five and six* hours, the temperature remained between 102 and 103 F. *for the* next few days, and subsequently returned to normal, with final restoration to complete health.

Case 2.—Child, 3 years old, with a history of chronic enterocolitis, with frequent acute exacerbations; was much emaciated; skin pigmented, suggesting complicating disease, profoundly anemic. The blood findings *negative*, except for simple anemia; child died within twenty-four hours after I saw it. Unfortunately, autopsy was denied.

---

[3] Allbut's System of Medicine, i, 821-831.

[4] System of Internal Secretions, etc., i and ii.

The temperature in this case was 106.6 F., and the pigmentation resembled somewhat that of Hodgkin's disease. It is not impossible that this may have been tuberculosis of the suprarenals.

Cases 3 and 4.—The next cases of special mention are two cases of measles, sisters, aged respectively 4 and 6 years, peculiar only in the fact that they had been healthy and well cared for; both were stricken at the same time and each had a temperature ranging between 106 and 106.4 F. on the afternoon of the second day; the rash did not appear until the afternoon of the third day, with the exception of a few slightly suspicious areas of erythematous rash, poorly defined, on the face and neck; Koplik's spots were present in the mouth, though few in number.

The temperature was reduced by cold baths, followed in each instance by being wrapped quickly in warm steaming blankets, which were followed in between five and six hours by a temperature ranging between 103 and 104 F., and subsequently by a natural convalescence and no sequels.

Case 5.—One of the cases of erysipelas is worthy of mention because of the age of the child, 8 months, and the rapidity with which the infection extended. First appearance of infection in the morning at 7 o'clock, on the lower third of the right leg; in two hours it had spread around the leg, forming a perfect zone one and one-half inches wide. This spread so rapidly both toward the foot and upper part of the body that in less than eleven hours the foot was completely involved and the extension upward had also reached the lower third of the femur. In thirty-six hours the whole leg, including the groin and the right side of the vulva, was involved. The temperature reached 106.2 on the evening of the second day, and again reached 105.8 on the morning of the third day; was reduced by wrapping the child in wet blankets wrung out of cold water and the injection of antistreptococcic serum, 500 units, on the afternoon of the first day; 1,000 units in the middle of the night of the first day; 1,000 units on the morning of the second day, and 500 units on the morning of the third day; this was supplemented with tincture of chlorid of iron, in small doses, of one and two drops, four times daily. Child recovered perfectly and is to-day in excellent health.

In the case of bronchopneumonia temperatures reach from 106 to 106.6. These cases exhibited their greatest interest in the fact that seven of them occurred in acute influenza, one in measles and one in whooping cough. High temperatures in bronchopneumonia accompanying influenza are not uncommon and are frequently above 105 F. In cases of whooping cough complicated by bronchopneumonia, hyperpyrexia is accompanied by a very high mortality.

Case 6.—Child, 3½ years old, and had whooping cough for three weeks, which was marked by rather severe paroxysms of coughing, hemorrhagic injections into the sclera and aggravated general bronchitis. The pneumonia developed at the end of the third week, following a rise of temperature which continued gradually until the third day of the pneumonic process, when it reached 106 F. The application of alternating cold and heat by means of wet blankets, protected, was resorted to with the result of reducing the temperature; the child died the following day.

Case 7.—Child, 13 years old, follicular tonsilitis, followed by a postpharyngeal abscess, in which the tonsillar involvement had been of rather indifferent and sluggish type, the temperature ranging between 101 and 102 F., returning to normal at the end of a period of nine days. Three days thereafter the temperature, preceded by a chill, suddenly rose to 105 F., falling to 103, and rose again the following morning to 106.2. Examination of the pharynx revealed a postpharyngeal abscess which was relieved and the patient recovered.

Case 8.—The case of scarlet fever was interesting from the fact that the rash was never fully developed and that the patient, a boy, 9 years old, was so toxic from the very first that he was never quite conscious six hours after the initial chill; he expired on the afternoon of the second day, with a temperature of 107 F. Little or no treatment was instituted here because the parents refused the application of hydrotherapy.

Case 9.—Perhaps no case in this list is of great interest than this. While all of us, possibly, have seen cases of hyperpyrexia occasioned by intestinal worms, but few of us, probably, have had the opportunity to see a case in which death followed, and in which the internal viscera were more or less infested by the parasites. In this case, A., a boy 9 years old, autopsy revealed a number of worms in the stomach, common and hepatic ducts; the temperature just previous to death reached 106.6.

Case 10.—This case had a temperature of 106.2, but by persistent purgation and the administration of santonin, etc., fifteen worms were discharged at different intervals, and the girl, 11 years old, recovered.

Speaking, briefly, of the general yet more or less special treatment of the average case of hyperpyrexia, one must have a definite conception of the patient's physical condition, natural resistance under normal conditions and temperamental control before selecting the form and frequency of the temperature reducing agent. Whilst hydrotherapy must form the principal safe means of temperature reduction, which should be modified in various ways to best meet the exigencies of the case, it will need to be supported by artificial heat and other forms of stimulating agents.

The primary exposure is of importance and should always be selected with reference to the physical and mental condition of the patient at the time of the treatment, so as to avoid too great a shock in its beginning. The methods may be selected to meet the patient's greatest comfort when the end to be accomplished is in no way affected by the means or methods employed.

The drugs to be employed should, at times, be supportive, at other times stimulating, and at still other times sedative; but at all times they must meet certain specific and definitely indicated requirements. Other agencies, such as artificial heat, oxygen, synapisms, etc., also have a place in the treatment of these cases and should be promptly applied when occasion requires.

The report of the study and observation of the cases of bronchopneumonia seen at the Infants' Asylum in the state of New York by Dr. Holt, in which hyperpyrexia was present in part of the cases, if studied from the relation of temperature to mortality, is not without added interest in this connection. It is declared that when the cases reached a temperature of 106 F. and more the mortality was 85.5 per cent.; between 105 and 106 F., 60 per cent.; between 104 and 105 F., 49 per cent.; between 102 and 104 F., 60 per cent.; and when the temperature never reached 102 F., the mortality was 71 per cent. These studies tend to prove that in bronchopneumonia high temperatures, under reasonable control, are protective rather than destructive, and though we have reason to believe that the normal resistance presented by this class of patients was far from being representative and of average comparison, nevertheless the mortality rate between 105 and 106 F. was not remarkably high, and between 104 and 105 F. was the lowest of the series. No doubt to-day, in the light of recent methods and advanced views on the subject, the mortality per cent. would be somewhat reduced.

Some of the facts set forth in the report are to the effect that in bronchopneumonia the highest and lowest extremes of temperature seen were the most dangerous, and a temperature between 104 and 105 F. was most protective.

For the purpose of further comparing the mortality rate of the cases reported by Dr. Holt, I merely call attention to a statistical report of 100 adult cases of hyperpyrexia treated at Guy's Hospital, London, by Dr. J. H. Bryant, in which the temperatures reached 106 F. and more, where the mortality rate was 84 per cent., and in the cases of bronchopneumonia it was 100 per cent. This would indicate that hyperpyrexia in adults with bronchopneumonia, considered from a small number of cases, is particularly fatal, more so than in children.

In my own cases the showing is quite a little better, due, no doubt, to the previous hygienic surroundings of the children and their out-door life and consequent robust resistance.

CONCLUSIONS.

The deductions to be drawn from the foregoing are:

1. That pyrexia is a complex phenomena occurring as a result of infection, injury, nervous shock or disturbance, the causal relations of which are as yet far from being wholly understood.
2. That hyperpyrexia is merely an aggravated pyrexia, and when present in certain diseases, such as bronchopneumonia, meningeal and pulmonary tuberculosis, pneumonitis or severe injuries to the nervous system is of grave significance.
3. That the rational use of cold water, properly sustained by artificial and internally stimulating agents, even in the extremely high temperatures, may, not infrequently, be followed by success.
4. That hyperpyrexia in children, though always signifying grave danger, is not so likely to be accompanied by fatal results, as in adults.

1616 Pacific Avenue.

ABSTRACT OF DISCUSSION.

Dr. T. W. Kilmer, New York: One point of especial importance is the application of cold packs. A favorite method of Dr. Kerley consists in the use of a bath towel with two holes cut in it for the arms. It is not wet when the child puts it on, so there is no fright. After being put on it is wet with water about 90 degrees, and later with water about 70 degrees. It is surprising to see how the temperature is lowered by the application of this cold pack. I know that one patient was kept in this pack for seventy-two hours, and I am sure that it was to this pack that the child owed its life.

PRESUMEDLY CURED GONORRHEA AND MARRIAGE.[*]

FERD. C. VALENTINE, M.D.

AND

TERRY M. TOWNSEND, M.D.

NEW YORK CITY.

Thirteen years ago it seemed timely to the senior writer hereof to sketch the dangers which apparently-cured gonorrheas[1] offer in the marriage-bed. It would be arrogant to tribute to that little effort anything more than the credit of being one of the early American papers on the subject. Other and better pens have since taken up the matter. The result is that to-day but few physicians will approve the marriage of a person who has had gonorrhea before all methods known to science to ascertain the presence of gonococci have proved negative.

Practitioners not especially trained in the study of genitourinary diseases are now asking specialists for the details of the all-important matter. It is in response to numerous demands for assistance that this paper is prepared. With a view to rendering the service as tersely as possible the magisterial tone is adopted and will therefore be pardoned.

THE HISTORY OF THE PATIENT.

A man who states that he observed the first symptoms of a gonorrhea within 48 hours after impure relations, is exposed to the suspicion of having then suffered a recrudescence of a preceding and perhaps forgotten infection or to have acquired the disease in a coitus within 8 or 10 days of the presumed cause. One in whom the first evidences of a specific urethritis appeared weeks or even months after coitus may have had a similar experience or may have failed to note the first manifestations of the disease. In the latter case it may have been a *blenorrhagie chronique d'emblée*, as Guiard calls what is ordinarily designated a "mild case." Parenthetically it may be observed that these so-called "mild attacks" often prove very rebellious. Discussion of the reasons for such rebelliousness is beyond the province of this paper.

Not infrequently an applicant for examination will tell that since the cessation of all symptoms of infection he has often had relations with women, among them several not given to sexual promiscuity. Indeed, his intimacies with one or another may have extended through prolonged periods, with the result that not one of them was infected by him. In explanation thereof several elements may enter, among which the most frequent only can here be mentioned. One woman contaminated with gonorrhea may have presented such slight manifestations of the disease that they passed unobserved, or she may have been perceptibly infected and have concealed her condition, to continue her hold on her lover; again, she may have had relations with another man, whom it might be more advantageous to accuse, and so on throughout the gamut of ignorance and cupidity. It would seem, however, fortunately for the human race, that a number of women, for a time at least, are immune to gonorrheal infection. No other explanation appears reasonable for the fact that some men, uncured of gonorrhea, marry without infecting their wives.

Let it be assumed, for present purposes, that the applicant for examination has had but one attack of gonorrhea. Let it be assumed, further, that for several years thereafter he observed no vestige of the disease. Nevertheless, it will be well then to subject him to tests which study and experience have methodized.

IRRITATION OF THE GENITOURINARY ORGANS.

With a view to obtaining all the evidence possible of what may occur in the course of nearly every man's life, the applicant is instructed to bring about as much irritation as he can by:

1. Eating freely of those things which he knows will disturb his digestion.
2. Drinking more champagne or beer than he usually consumes, but not to the extent of inebriation. If he is an abstainer or if the consumption of any quantity of alcohol easily leads him to inebriety, he is advised to consume very large amounts of carbonated beverages instead.
3. Inordinate physical and mental work, late hours.

dancing, bicycling and horseback riding will contribute to irritating the genitourinary organs and thus enhance the intensity of the irritation.

These tests should be carried to the extreme of the applicant's endurance. It will be well to extend them over a week or ten days. If perceptible disturbance, such as even a slight excess of urethral secretion, or even discomfort on urination, arises before the expiration of the period mentioned, it will be in order to proceed with the next step of the investigation.

URETHRAL SPECIMENS FOR MICROSCOPY.

The patient is ordered to present himself before voiding his first morning urine. If for any reason, such as the distance of his residence or the need of very early rising, prevent this, the patient is provided with sterilized, blunt tooth-picks and microscopic slides and instructed in the technic of taking any excess of urethral secretion that may present. He is also provided with six 3-oz. (90 c.c.) clean bottles with clean corks, and instructed to pass into them his first morning urine. He is further instructed to write his name or other distinguishing mark and the date on the labels of the bottles, and to number the succession in which each bottle is used.

When the patient can come to the office before having voided his first morning urine, the urethra is stripped according to the technic described elsewhere.[2] Should stripping fail to bring an excess of urethral secretion to the meatus, the urethra may be curetted with a sterilized platinum loop and the results finely spread on a flamed cover-glass for microscopic examination. At the same time that a specimen is obtained for microscopy one or more slants of Loeffler's serum are inoculated by stabs and streaks and put into the culture oven immediately. They are kept at 99 F. Some of our colleagues deem room temperature sufficient for the purpose.

The patient is then instructed to half fill a 12-inch (180 c.c.) ignition tube with his urine and entirely fill as many more tubes as he may need to almost empty his bladder. The remaining quantity is passed into a final tube. As the patient has used each tube it is immediately stoppered with sterile cotton and marked by means of a "glass pencil" with the patient's name and numbered to designate its place in the succession of tubes used. If the urines intervening between the first and the last are perfectly clear and contain no "floaters" and if the first and last suffice for exhaustive microscopy, the intervening tubes may be discarded. The saved first and last urines, even if microscopically clear and free from "floaters," should be sedimented and the result prepared for microscopic examination.

SPECIMENS FROM PROSTATE AND SEMINAL VESICLES.

If the preliminary preparation of the patient has not resulted in a recrudescence of the discharge, the prostate may be massaged and the seminal vesicles stripped for specimens[3] in addition to those taken from the urethra. The contents of the adnexa mentioned, as they present at the meatus, are used for microscopic specimens and culture. Should no secretion be immediately obtainable by massage and stripping, the patient is instructed to walk about for a few moments; usually a slight oozing at least then presents. If this does not occur, the urine passed within five or ten minutes thereafter will be found in most instances to be loaded with the secretion that has not escaped ("Expression Urine"—Posner). Specimens herefrom are then available for microscopy.

URETHROSCOPY.

If within three days autoreinfection of the urethra has resulted, the discharge must be taken for microscopy and culture. If no reinfection has occurred, exhaustive urethroscopy is demanded. Specimens for microscopy and culture are then taken from any enlarged crypts or follicles that may be discovered. The most convenient means for pumping the secretions from the adnexa is the Kollmann gland aspirator.

Even if all the specimens obtained and cultures made prove to be free from gonococci, the presence of the infectious microbe is not to be entirely excluded, as it is just possible that all these may have happened to contain none of the microbes. For additional safety all the proceedings described should be repeated two days after the urethroscopy.

ARTIFICIAL LOCAL IRRITATION.

Both sets of examinations proving negative, further steps are indicated. An anterior irrigation with mercury bichlorid, 1 to 5,000, generally suffices to set up quite a severe urethritis, which is easily controllable by a few irrigations when no gonococcal invasion of the urethral stroma has occurred. When, however, the provoked discharge contains gonococci, the question under consideration is decided. Some urethræ show a marked tolerance of the bichlorid of mercury; it then fails to cause a discharge. Usually an injection with silver nitrate (1 per cent.) retained for five minutes will serve the purpose where the mercuric bichlorid fails.

THE SEDIMENTED URINE.

When examination of all genital secretions or hypersecretions fail to show the presence of gonococci, the sediment of urine may show the presence of the infectious microbes. The site where they are held residual must then be determined by repetition of the researches already described.

QUESTIONABLE MEANS.

In some countries the examination is not deemed final until the applicant has several times performed the sexual act with condums and has brought these with their contents for microscopic and cultural examination. We who ever have an innate repugnance against counseling extramarital coitus, especially to a man about to marry, do not care to avail ourselves of this test. This test is unpopular with patients and frowned on by the profession in this country. Whether this is due to innate morality, to delicacy or to prudishness is not now under discussion. We have, however, rarely found it expedient to avail ourselves of this test. The exception is whenever we are convinced that the individual presenting himself for examination has no intention of observing continence even on account of the approaching marriage. Ours would be a false morality did we fail to avail ourselves of his known weakness by suggesting that, should he indulge, it would be advisable to use a condum in order that its contents may be subjected to microscopic and cultural examination.

The future will decide the value of opsonic methods in determining the presence of gonococci. The time is not yet ripe for its discussion in a mere sketch like this.

[2] The Irrigation Treatment of Gonorrhea: Its Complications and Sequelæ. William Wood & Co., New York, pp. 202 et seq.

[3] Massage of the Prostate and Stripping the Seminal Vesicles: Med. Rec., June 29, 1907.

All the tests proving negative, the series should be repeated a month or two later. If the second series of investigations expose no evidence of the presence of gonococci, it is fair to assume that, as far as present-day science can determine, the applicant may marry with safety to his future wife. Little beyond a mere inventory of the steps necessary to decide the all-important question has been offered. Even as such this paper has several specific objects:

OBJECTS OF THE PAPER.

1. The discussion, with which it may be honored, will bring forth the means employed by abler students to determine the momentous questions involved.

2. General practitioners, guided and advised by those who may by their comments give this paper value, will everywhere urge their ex-gonorrheics to be examined before contracting matrimony.

3. Marital communication of gonorrhea will consequently be much reduced and a vast amount of misery and death of innocent women eliminated from the trail of the disease.

4. The state will be spared the maintenance of an uncountable number of dependents.

5. Sanitary science will be advanced by its aid in combating the effects of a disease which can not come within the scope of sanitary enactments.

ABSTRACT OF DISCUSSION.

DR. J. M. **BEFFEL**, Milwaukee: I believe that the subject of this paper is the most momentous problem we have before us at this time. When we consider that fully 80 per cent. of the abdominal operations performed on women are due to gonorrhea contracted almost invariably innocently on the part of the women; that throughout this country almost 50 per cent. of the men between twenty and forty have had gonorrhea; that it is almost incurable, and that these men are constantly having this morning drop, and are not cured at all; when we look into the structure of the urethra, and realize that it is not a simple tube, but has folds and crypts in it, into which an antiseptic cannot reach at all; that it has twenty or more openings, and that the whole tract may be affected, from one end to the other, and that antiseptics can never reach those recesses, then it seems to me that this problem becomes one of the most important problems we have to meet. I am convinced that the general practitioner is not treating gonorrhea correctly, and that is the reason why the gynecologist is thriving as he is to-day. Fully 80 per cent. of the gynecologist's work is due to gonorrhea. When we take up another side of this problem, and realize that 40 per cent. of all the blindness in our asylums is due to gonorrhea, we must conclude that here is another enormous burden. In all probability deafness and consequent dumbness are frequently the result of infection of the ear by the gonococcus. So I say this paper is the most timely paper that has been presented to-day, tuberculosis and typhoid fever and all these subjects to the contrary notwithstanding. I do not believe we appreciate the magnitude of this problem. I think that I can safely say that no practitioner who watches a case of gonorrhea microscopically will ever be willing to give a person afflicted with gonorrhea a clean bill of health to be married. I have seen a large number of patients who have gone for months absolutely without any evidence that they had the disease, but when the prostate was thoroughly squeezed a discharge was yielded which was more or less rich in gonococci. In all the cases that I have treated, when the gonorrhea has run a course of more than six months, I have failed to find one, even though for six or eight months there had been no discharge, in which gonococci were not yielded in the prostatic secretion. The patient may even live a more or less irregular life without any symptoms of his gonorrhea, and yet the gonococci may be amply present in his prostatic secretion. As we come to use the microscope more, and express the secretion more carefully, we shall realize more and more the tremendous extent and persistency of this disease, which has received in past years altogether too little attention from the medical profession and from the laity.

DR. R. S. **YARROS**, Chicago: In the past the average physician has neglected his duty alike to the patient and his possible innocent victim; although knowing the dangers of gonorrhea, he has seldom told the patient the certainty with which this disease is communicated and the greater danger of the disease to infected women. But fortunately, there has been of late a moral awakening among the profession and the lay public as well with reference to this question, and the physician has no further excuse for shirking his duty. We have done considerable work in this city under the auspices of the Society for Social Hygiene and the Chicago Women's Club. A body of women have gone before most of the women's clubs in the city and suburbs, giving lectures on this subject, which have been received with great interest. It seems to me that it is the duty of the men in the profession to undertake a systematic propaganda among men. Each patient must be told of the dangers of his disease to those he might infect unknowingly and unwillingly. We must insist that a man who has gonorrhea shall not marry until he is cured, and in extreme cases, in which the patient refuses to take this advice, the innocent person must be given warning in some way. The time has come when we should take this definite stand to protect the innocent.

DR. O. C. **BREITENBACH**, Escanaba, Mich.: Attributing criminality to the transmission of venereal disease by either male or female, does not materially benefit the situation. Venereal disease is a social problem even more than a medical question. We all know the tenacity of a gonorrheal infection, and that this specific infection entails untold misery to those originally infected and to their offspring. The cure of gonorrhea is problematic, and therefore prevention of infection is of the highest importance. Education is the most efficient means toward this end. The American Medical Association and many of our state medical societies are putting forth efforts in this direction. It is gratifying to note the efficient cooperation of the laity. The efforts of Felix Adler, Graham Taylor, Jane Addams and many others promise good results.

DR. H. B. **HEMENWAY**, Evanston, Ill.: Several years ago a prominent druggist, who had been in the business thirty years, and who might naturally be expected to be better informed than the average man, asked me a question about the general dangers of gonorrhea. I suggested that heart disease might come from gonorrhea, and he was greatly surprised. He had been accustomed from time to time to accommodate his friends by putting up a mixture for treatment. When I met him not long ago he said: "From that day to this I have not dared to give any medicine for gonorrhea; I have sent inquirers to the physician." The real way to get at this subject is not simply to tell the doctor that he must instruct individual patients in what they must do, but to give general education. To-day a good share of the education in this line of work is given by very questionable publications that are distributed on the street corners or through the mail sometimes. The real and genuine education has been too much neglected. It is by talks in such associations as the Y. M. C. A., and through the regular publications, that the best education must come.

DR. J. N. **HURTY**, Indianapolis: We have a judge of the Indiana Supreme Court who stated that from his observations he had come to the conclusion that venereal diseases had an effect on crime and on insanity. He had watched many cases all the way from the lower courts to the Supreme Court, and after studying the matter, came to the conclusion that treatment of the disease would not be effective. I think that he is about right. It must be treated, of course, but that will do nothing or at least little toward prevention. What is to be done? Educate, you say. That is a long route, but it is the only one that seems to be left open to us. The judge to whom I have referred drew up a law, which was passed, making it illegal in Indiana for any person afflicted with venereal disease to marry knowingly. The State Board of Health has prepared a series of cards, which we call our red cards, one referring to gonorrhea and the other to syphilis.

These cards are distributed throughout the state to be handed by physicians to those who apply for treatment. I was once in a doctor's office when he received the cards, and he immediately threw them into the waste-basket, for he said that he would not cut off one source of his revenue. We have heard it said that pharmacists treat these diseases. I know that they do, for I spent a good part of my early life in a pharmacy. But what can be done? For a license to marry in Indiana one must go to the county clerk. We have, therefore, been instructing the county clerks about the prevention of the venereal diseases, so they might impress their responsibilities on young men and those who apply for licenses. At the present time both parties must, before a license is issued, swear to their best knowledge and belief they are not afflicted with any communicable disease. As yet I do not suppose much effect has been produced, but I hope that some time in the very near future we can report from Indiana a diminution in these terrible diseases, due to the efforts now being made.

Dr. A. H. Burr, Chicago: I read a paper before this Section two years ago on "The Guarantee of Safety in the Marriage Contract," in which I called attention to the weakness and the failure of the Indiana law to bring about definite results. As far as the Indiana law went, it was good, but it did not go far enough. As you have heard from the last speaker, the men who diagnose the cases are not physicians. The applicant diagnoses his own case, and he is not going to confess to any venereal infection. It is not to his interest to do so. He swears that, to the best of his knowledge and belief, he is not a victim of the disease. He may have had it, and think he is cured, and yet may be incurable. The trouble with the Indiana law is that there is no board of examining physicians, and the applicant passes through no process of investigation to know whether he is a victim of an incurable disease or not. If Indiana had a law like that of North Dakota, with an examining board, so that every candidate for a license to marry must present a certificate signed by two physicians of the examining board, it might prevent some of these diseases from being transmitted through marriage. I have seen the cards of which Dr. Hurty speaks. Some were sent to me by the secretary of the Indiana State Board of Health, and I take great pleasure in handing one to every patient with venereal disease that comes into my office.

Dr. Ferd C. Valentine, New York: A speaker holds that gonorrhea is practically incurable when the whole genitourinary tract is involved. Study and experience do not allow me to agree with this view. But, when gonococci invade the endocardium or the fourth ventricle of the brain, no remedy is known for the disease. Another speaker says that gynecologists thrive because general practitioners do not treat gonorrhea properly. Since specialists have done so much to teach the proper management of gonorrhea, the average general practitioner uses his best efforts in each case brought before him. The reason for the large amount of work that goes to the gynecologist lies in the public attitude. As yet relatively few men regard it as a moral duty to be examined before marriage. Indeed, it requires more than ordinary intelligence to appreciate that long after all crass manifestations of gonorrhea have disappeared, the patient may still be able to infect his wife. To obtain statistics regarding gonorrhea would entail reporting every patient with gonorrhea to the board of health. This would, in most instances, reveal the patient's immorality, break up homes, destroy the happiness of wives, deprive children of their fathers and involve violating our most sacred obligations. Rather than do these things, I would defy such a law and suffer incarceration for infringing it. The statement that no general practitioner would give a gonorrheic a clean bill of health led to the preparation of the paper we are discussing. The general practitioner is seldom called on to examine a patient before marriage. The reason is largely that the general practitioner, not being specially instructed in the technic of such examination, usually refers his patients to competent specialists. There are not, and there never can be, enough genitourinary specialists to treat gonorrhea. It therefore behooves the general practitioner everywhere to familiarize himself with this disease, and to examine his patients who have had active gonorrhea to determine whether they harbor residual gonococci. The man who has acquired gonorrhea is often unthinkingly condemned. Optimism and humanitarian sentiments demand a consideration of the matter in its true light. The majority still hold that for the male premarital sexual relations are natural. Whatever the cause of his acts, no man deliberately sets out to acquire gonorrhea. It is outside the province of the physician to act as the judge of such unfortunates. It is our duty simply to prepare ourselves to treat gonorrhea properly, and while so doing to endeavor to raise the patient's moral tone. It has been said that it should be the physician's duty to inform the woman with whom a gonorrheic intends to have legal or other sexual relations, of the fact of his infectiousness. I know of no means by which the physician could obtain information of the intention; and, if he could, nothing could excuse the violation of professional confidence. Moreover, the woman would resent the warning. The work of educating the public is being so excellently performed by our American Society of Sanitary and Moral Prophylaxis that a hope to see its membership reach a million in the next year or two is fully justified.

It is regrettable that Tarnowsky's "Prostitution und Abolitionismus," one of the most important books on this subject, has not yet been translated into English. It quotes anthropometric studies of 500 prostitutes, every one of whom had at least one stigma of degeneration. Thus prostitution was stamped on them before birth. Fournier has shown that public prostitutes disseminate venereal diseases less than do others. The greatest number of men are infected by clandestine prostitutes: they are beyond the reach of the written law or of moral precepts.

THE CLINICAL VALUE OF THE SPIROCHÆTA PALLIDA IN THE DIAGNOSIS AND TREATMENT OF SYPHILIS.

FREDERICK G. HARRIS, M.D.
Adjunct Professor of Dermatology, College of Physicians and Surgeons, Medical Department, University of Illinois.
AND
B. C. CORBUS, M.D.
Lecturer on Dermatology and Genito-Urinary Diseases, Post-Graduate Medical School.
CHICAGO.

When Schaudinn[1] in 1905 described the *Spirochæta pallida* as the probable cause of syphilis, the study of that disease received a new stimulus. As usual, the discovery of the cause of a disease is followed very shortly by a broadening of our knowledge of that disease. So it has been with syphilis. The research and experiments which were stimulated by Schaudinn's report and made possible by the discovery of Metchnikoff and Roux[2] in 1903 that syphilis could be inoculated into the higher apes, have already illumined so many of the dark places of this protean disease that the time seems to be not far distant when syphilis will be given a rational pathology and a logical therapy.

For the practitioner animal inoculation has merely a scientific interest. The demonstration of the spirochete on the other hand, has the same significance for syphilis that the presence of the tubercle bacillus has for tuberculosis or the gonococcus has for gonorrhea, and the demonstration of the spirochete is just as essential for diagnosis—in fact, in the case of primary syphilis is even more essential.

That the *Spirochæta pallida* is the true etiologic factor in syphilis, all who have followed the literature must concede. It would be impossible to give here a résumé of all the work that has been done on this subject, the bibliography being already very extensive. The following facts represent briefly the principal reasons for considering the organism specific.

---

[1] Arb. a. d. k. Gsndhtsamte, 1905, xxii, No. 2, p. 527.

[2] Ann. de l'Inst. Pasteur, xvii.

1. It has been found innumerable times by observers in all parts of the world.
2. It has only been found in syphilitic, never in nonsyphilitic lesions.
3. It has been found in the lesions of every stage of syphilis, even in the gummatous or so-called tertiary stage.
4. It has been found in every type of syphilitic lesion.
5. Syphilitic material containing spirochetes has been inoculated into monkeys and the spirochete demonstrated in the lesions so produced. Material from these lesions produced the disease in a second series of monkeys and so on for forty-two successive inoculations, all the lesions of which showed the spirochete.[3]
6. Human material containing the spirochete gives the reaction for antigen with the serum of syphilitics.

It is a fact that the medical profession of the United States has been rather loath to accept the spirochete as the specific cause of syphilis. Those of the profession who have accepted it have not appreciated the great value of the organism as an aid to diagnosis and treatment. One reason for this has been the difficulty of staining the organism, as is evidenced by the numerous methods advocated for that purpose, none of which is very reliable. By the best method the organisms stain so faintly that it usually requires a prolonged search to find them. Again, it is very difficult to differentiate the stained specimen from other spirochete-like organisms. Hoffmann, Schaudinn's collaborator in the discovery, has emphasized this difficulty and he says that in a stained specimen the diagnosis should only be made by an expert, one who by close familiarity with the organism has acquired an intuitive knowledge of its morphology. It is a fact that the stained specimen lacks some of the characteristics of the living organism, chief of which are:

1. In the stained specimen the organisms are much less numerous than when the same material is examined fresh.
2. The method of preparing the specimen causes the organisms to lose to a certain extent the acute winding of the spirals, which is so characteristic of the living organisms.
3. Probably one of the greatest disadvantages of the stained specimen is the absence of motility. The motions of the spirochete are very characteristic and are of inestimable assistance in differentiating the pale from other spirochetes.

THE DARK GROUND ILLUMINATOR.

A much more convenient as well as infinitely more reliable method of demonstrating the organism is in the living state, by means of the so-called dark ground illuminator. This method was described by the Rev. J. B. Read in 1837, who used practically the same apparatus that we are using to-day. Read described his method just at the time that Professor Abbé brought out his well-known substage condenser and in the excitement over Professor Abbé's invention the dark ground illuminator was forgotten until rediscovered by Reichert, the microscope manufacturer of Vienna, in 1907.

The advantage of this method depends on the illumination, the principle of which is the same as that causing dust particles to become visible when passing through a beam of sunlight.

The apparatus of Reichert (Figs. 1 and 2) consists of a metallic plate (Fig. 2, A), having a hole in the center, above which is fitted a piece of glass (Fig. 2, B), having a circular excavation on its under surface; the sides of this excavation are ground at a certain angle and silvered (Fig. 2, C, D). By means of a revolving disc (Fig. 2, E) different sized diaphragms are used to cover the central part of the excavated area, so that when the light is reflected up from the plane mirror of the microscope, only the marginal rays reach the glass plate. These impinge on, and are reflected by the silvered sides of the excavation to a central point 1 mm. above the surface of the glass plate. Any solid body here will intercept these rays and appear as luminous objects on a dark ground. By this method it is possible to see the particles of colloidal substances in their solutions.

THE REICHERT INSTRUMENT.

A form of dark ground illuminator is now manufactured by most of the microscope makers, but the Reichert instrument is superior to others for the following reasons:

1. It can be used on any kind of microscope.
2. By means of the revolving diaphragm the amount of light may be varied at will.
3. It is possible to change from the dark ground method to the ordinary method of transmitted light by merely revolving the diaphragm.

The method of using the apparatus is as follows:

The Abbé condenser is removed. A strong light is necessary; one may use sun or arc light, a Nernst lamp, or an inverted Welsbach. Except with the sun or arc light, a six-inch condenser lens is necessary, or a large glass globe filled with water serves the same purpose. The illuminator is placed on the stage of the microscope, and by means of the low power the circle which is etched on the glass plate is brought into the center of the field and the apparatus fixed in this position by means of the clips on the microscope. A drop of immersion oil, free from air-bubbles, is placed on the center and the prepared slide put in place. great care being taken to avoid the formation of air-bubbles. When the preparation is examined with the low power, if the light is placed right and the apparatus centered, one observes a bright central point. The high power is now turned on and the field is seen to be dark, with luminous points and bodies.

PREPARATION OF THE SPECIMEN.

The method of preparing the specimen is very important. The slide must be 1 mm. thick, and both slide and cover-glass must be perfectly clean and well polished. as any turbidity or scratches disperse the light and cause annoying halos, which prevent the dark ground effect or interfere with the examination. Air-bubbles in the specimen also cause these disturbing effects. The specimen must be as thin as possible. The observation is best made with a dry system. We use a Leitz 1/8-inch objective and a No. 5 ocular. One can use an oil immersion; in this case. however, it is necessary to diminish the aperture of the objective by inserting a truncated cone back of the front lens of the objective. This cuts out the diverging rays of light, which otherwise would flood the field. For diagnostic purposes we have seldom found it necessary to use the oil immersion.

---

[3] E. Finger: Personal communication.

METHOD OF OBTAINING THE MATERIAL.

For chancres, mucous patches and condylomata it is sufficient to clean the lesions thoroughly with warm water. They are then irritated by being rubbed vigorously with a piece of cotton wrapped on a probe. This causes an abundant exudation of serum. A small drop of this is placed on a cover-glass, which is now carefully inverted onto the slide as in making a fresh blood preparation. It is well not to have much admixture of blood, as the blood cells interfere somewhat with the observation. For cutaneous lesions one may take a drop of blood from the lesions and often find the organism. The best method, however, is to scarify the lesion down to the papillary layer and then apply a small cupping glass. The abundant exudate of serum usually contains numerous spirochetes.

On looking at a specimen containing serum from a chancre one sees numerous small, round luminous bodies which have a very active Brownian movement. These particles of albumin are probably identical with the blood-dust of Müller. If the cleansing has not been thorough, one often sees various forms of bacteria, the cocci looking like pearls. The leucocytes are seen as a mass of white granules surrounding the dark nucleus, the various forms being easily differentiated. One often sees the ameboid movement and the granules in an active Brownian motion. The red corpuscles show as a luminous ring surrounding a central pale reddish zone.

CHARACTERISTIC FEATURES OF THE SPIROCHETES.

The spirochetes are typical, much more so than in the stained specimen, and are exact duplicates of those stained by the Levaditi method. The most characteristic features are:

1. *Size:*—They vary in length from 7 to 21 microns, being from 1 to 3 times the diameter of a red blood cell. It is not uncommon to see the organism longer than this, but on account of the difference in the motions of the two extremities, we believe these long forms are composed of two or more individuals.

2. *Shape:*—They are seen to consist of an extremely slender thread closely wound in a corkscrew or spring form, the windings being very acute. In the fresh specimen the windings are absolutely regular, but as the specimen gets older the organism changes form, the most frequent change being an obliteration or irregularity of the windings in the central portion. This is a very common appearance in the stained preparations.

3. *The Ends:*—These are sharp and terminate on the periphery of the spiral and not in the center, as the *Spirochæta buccalis* and some of the other forms do. This peculiarity of the ends is only seen when the organism rotates on its long axis

4. *Motility:*—When the specimen is freshly prepared the organism is very active and possesses the following motions: (a) A rotation on its long axis in either direction; this motion is very rapid but not necessarily accompanied by a change of position; as the specimen gets older this motion grows less. (b) It progresses from place to place but not so rapidly as the other forms of spirochete commonly met. (c) They have a bending or twisting motion which is quite quick and spasmodic. This form of movement increases as the specimen gets old and at times one sees an organism bent in the form of a circle, resembling somewhat a crenated red blood corpuscle. It is not uncommon to find two organisms joined end to end. In fact this arrangement is so common that it lends some weight to the view that the organism multiplies by fission. Again, one sees two or three organisms lying side by side. We have never found the spirochete in a red or white blood corpuscle as described and pictured by some observers in the stained specimen, and we are inclined to believe such appearances are artifacts.

The number of organisms found varies in the different lesions. They are most numerous in chancres, condylomata and mucous patches and vary from two or three in a field to sixty or eighty. Cases that have received some treatment show fewer organisms than the untreated ones. A few days local treatment with calomel or other mercurial preparations causes a marked diminution in the number present in the chancre, although they are very numerous in the enlarged inguinal glands. Among the cutaneous lesions, aside from the condylomata and mucous patches, the ulcerative syphilides show the most organisms. As a general rule, one may say that the more succulent the lesion the more numerous are the organisms.

In several patients having large placques on the tonsils we found the sputum teeming with the organisms, and in these specimens one can study the differences bebetween the *Spirochæta pallida* and the *S. buccalis* and *S. dentium*. We have never been able to convince ourselves of the presence of cilia or of an undulatory membrane, although there are times when one is suspicious that the latter might be present.

The organism when fresh is very active, but in about three-quarters to one hour after preparing the slide the movements become spasmodic and much less frequent and malformations occur. We have kept the organisms at the room temperature for two weeks or more, but at the end of that time one could not say whether or not they were alive, they certainly were not motile and had not multiplied. In capillary tubes we have had the organisms remain alive and motile for twelve hours at the room temperature.

The *Spirochæta pallidæ* as seen by this method, after some experience, are not difficult to differentiate from other organisms. The older the specimen the more difficult it is. The fresh specimen is very typical, and by close study of the size, windings and movements can be differentiated from other forms. The thread is much thinner, the windings more acute and the motility, as to locomotion, less than the other forms met. We have often seen a very much thinner and shorter body, that seems to have an extremely rapid rotary motion, which gives it the appearance of having a spiral form with knobbed ends. Its bending motion is marked but its locomotion is poor. These bodies vary greatly in size and are very common. As to their identity and significance we are unable to make any statement. We have found them in both syphilitic and non-syphilitic lesions.

LESIONS EXAMINED.

We have examined 160 lesions in 139 cases for spirochetes. The material was obtained from Dr. W. A. Pusey's service at the County Hospital, Dr. W. L. Baum's clinic at the Post-Graduate Medical School and from our private practice. Of the 139 cases 76 were clinically syphilis, in 59 of which we found the spirochete. (See Table 1). The lesions examined were as follows:

Chancres, 23; spirochetes were present in all.
Flat condylomata, 21; spirochetes present in all.
Mucous patches, 19; spirochetes present in all.

Cutaneous syphilides of various sorts, 33, in only 16 of which were we able to find the spirochete.

We found the spirochetes in two cases in which we punctured the enlarged inguinal glands.

Plus marks indicate the relative number of organisms present.

It will be observed that the organisms were always found in chancres, mucous patches and condylomata. The seventeen cases in which we failed to find the organism were mostly cutaneous lesions (see Table 2), most of which were late forms and many had been on antisyphilitic treatment. As we now know that all foci of syphilitic inflammation contain the spirochetes, we believe our failure to find them in these seventeen cases was due to a faulty technic. At first we scarified the lesion and examined some of the serum and blood so obtained. This method not proving very successful, we tried to get serum by applying a minute cantharides plaster over the center of the lesion. This method was somewhat more successful but still not all that could be desired. Recently we have returned to the scarification, but in addition we use a cupping glass as described above. This method affords an abundant exudate of serum, which often contains numerous spirochetes. We have no doubt that if we had used this method in our earlier cases we should have found the organism in practically all of the cutaneous lesions.

VALUE OF EARLY DIAGNOSIS.

Among the syphilitic cases are several which are especially interesting. Number 18, Table 1, shows the great practical value of this method in the diagnosis of primary lesions. It was that of a married man who presented himself with two ulcers, the largest less than 1 cm. in diameter, on the foreskin, of five days' duration. There was slight inguinal adenopathy on the left side. Instead of waiting six weeks or two months to see if secondaries developed, we examined some of the serum from the ulcers and found it teeming with spirochetes. The chancres were excised and the patient immediately put on anti-syphilitic treatment. The wounds healed by primary intention and there have been no signs or symptoms of the disease since.

This line of procedure might give rise to some criticism, in answer to which we would say that this seemingly radical treatment was not undertaken with the hope that we could certainly prevent the systemic invasion, for, although we had no evidence of such dissemination having taken place (the inguinal glands being so small as to make it questionable as to whether they were infected), we believe that a logical therapy would indicate the removal of the known source of absorption and the institution of immediate treatment would destroy any organisms which had progressed beyond the local focus. At least after demonstrating the ulcers to be syphilitic, this procedure might possibly prevent a dissemination and certainly would prevent from six to eight weeks intoxication and limit the dissemination of the virus. This line of treatment was particularly valuable in this case, as the patient soon ceased to be a source of danger to his family. (See also case No. 3).

After the primary sore has been found to contain the *Spirochæta pallida* by a competent observer we believe excision, when possible, and when not possible deep cauterization, and in either case the immediate institution of anti-syphilitic medication is the proper and logical treatment. Nisser[4] in recording some animal experiments along this line advocates the excision treatment when possible. It is possible in almost all cases except those in which the initial lesion is on the lip, finger or glans penis.

It is just here that this method of demonstrating the organism of syphilis will find its greatest usefulness, for we will no longer be compelled to make use of what Jullien has called a "scientific monstrosity" and wait until the system is saturated with a virus before commencing treatment. Who can say what effect the institution of a logical therapy, commenced early in syphilis, may have on the development of the so-called parasyphilides? Is it going too far to predict that when this line of treatment becomes general, cases of tabes and paretic dementia will become medical curiosities and the incidence of cardio-vascular disease will be greatly lessened? In fact is it not possible that all those diseases in which syphilis plays an etiologic rôle will become less frequent?

Although the greatest value of this method of demonstrating the *Spirochæta pallida* is in the diagnosis of chancres, it is also of immense value in controlling our cases while under treatment. It is a common thing for a case of syphilis, while under treatment, to develop a lesion on some part of the body, most commonly in the mouth, and it is extremely important to know whether such a lesion is syphilitic or not. *Adequate anti-syphilitic treatment presupposes the absence of all syphilitic lesions.* A case in point is the following: A man (Case 69, Table 1), whose infection was of 1½ years' duration, had received a course of inunctions, a course of injections and also a course of protoiodid pills. Three weeks after ending his course of pills he presented himself with what he called a "cold sore" on the lip. Examination of serum from this innocent looking sore showed numerous *Spirochætæ pallidæ.* Without this examination one might have thought that the lesion was in reality a "cold sore" or a mercurial ulcer, when it was in fact a mucous patch and instead of the patient receiving too much mercury he was not getting enough. Cases Nos. 70, 73 and 77 were similar ones, all of which had been on treatment for from one to three years, and in spite of this we were able to demonstrate the spirochetes in the mouth lesions. We could cite numerous other cases showing the great practical value of the spirochete as an aid to diagnosis and treatment, but they will form the subject of a future communication.

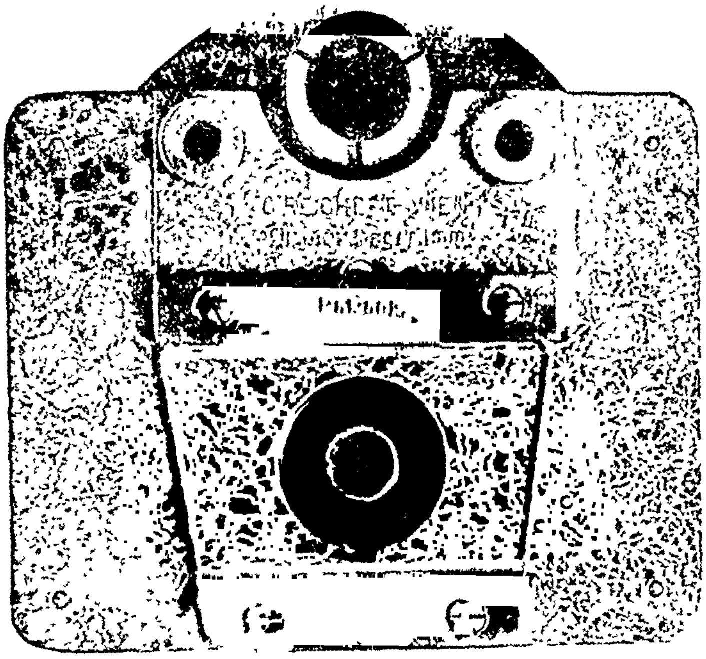

Fig. 1.—The Reichert apparatus for "dark-ground" illumination; to be attached to the microscope stage.

NON-SYPHILITIC CASES EXAMINED.

Among the non-syphilitic cases examined were: Thirty-six chancroids; 2 cases of traumatic ulcer of the penis; 1 case of carcinoma of the rectum; 4 cases of mercurial stomatitis; 2 cases of catarrhal stomatitis; 1 case of rodent ulcer; 3 cases of balanitis circinata; 1 case of chronic connective tissue hyperplasia of the vulva; 2 cases of exudative erythema with lesions of the buccal mucous membrane; 2 cases of herpes labialis; 1 cases of herpes zoster; 1 case of pemphigus vulgaris; 1 case of dermatitis; 1 case of erythrodermia; 1 case of blastomycosis; 1 case of elephantiasis of foreskin; 2 cases of psoriasis. In all of these cases the spiorchetes were absent, although clinically many of them were suspicious of syphilis.

In the case of chancroids a negative finding does not exclude syphilis, for the reason that the period of incubation of the chancre might not have passed. Most of the hospital cases of chancroids we were unable to follow, none of our private cases ever showed any manifestations of syphilis.

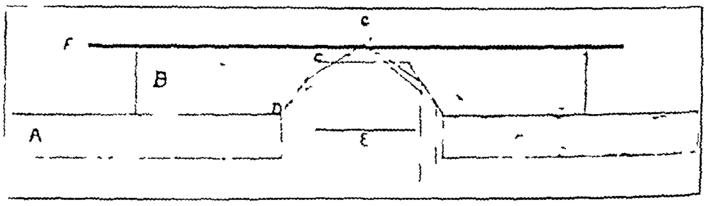

Fig. 2.—Diagram showing the principle of the "dark-ground" illuminator. A, metallic plate; B, glass plate; C, D, silvered sides of aperture in glass plate; E, diagram; F, microscope slide; G, objective.

There has been a great deal of discussion as to the spirochetal nature of the objects obtained by the Levaditi method of staining. A comparison of the living organism with those obtained by the Levaditi method will show that they are identical and immediately disposes of the suggestions that the Levaditi organisms are artifacts, nerve fibrillæ, cell borders, etc. That this method of finding the organisms is a great advance over all staining methods will be readily appreciated by all who have made the long, tiresome search with the old methods. Also the spirochetes are so much more characteristic that the differentiation is not at all difficult.

We have made some agglutination experiments, but as yet have not obtained the same results as Zabolotny,[5] who has reported the agglutination and disintegration of the spirochete with syphilitic serum. We hope to be able to report more definite results along this line.

CONCLUSIONS.

As a result of our investigations we believe we can draw the following conclusions:

1. The *Spirochæta pallida* is the true cause of syphilis and its presence is equivalent to the diagnosis of syphilis. Its absence does not rule out syphilis.
2. The silver spirochetes are true organisms.
3. By means of this method the spirochete may be demonstrated in all primary and secondary lesions of syphilis, if the search is persistent.

[4] Die experimentelle Syphilis-Forschung nach ihrem gegenwärtigen Stande, Berlin, 1906.

[5] Russk. Vrach., 1907, No. 6.

4. *After demonstrating the organism in a primary lesion it is not only unnecessary but harmful to wait for secondary manifestations. The most logical therapy is excision of the chancre when possible, and in all cases the immediate institution of the vigorous antisyphilitic treatment.*

In conclusion we wish to call attention to the great value of the dark ground illuminator for the demonstration of the *Spirochæta pallida* and to emphasize the necessity and value of the demonstration of the spirochete in the diagnosis and treatment of syphilis where there are accessible lesions. In suspected cases with no lesions and in cases in which there are cutaneous lesions, in which we fail to find the spirochete, we have found the Wassermann serum diagnosis of great value. As it is, these two procedures practically give us control of the diagnosis of syphilis, and it is to be hoped that the near future will give us a reliable method of detecting syphilitic antigen and thus furnish us with an absolute method of saying when the disease is cured.

CEREBELLAR SYMPTOMS IN HYDROCEPHALUS;

WITH A PATHOLOGIC REPORT OF A CASE ASSOCIATED WITH SYRINGOMYELIA.[*]

JOHN H. W. RHEIN, M.D.
Neurologist to the Howard Hospital; Physician to the Philadelphia Home for Incurables.
PHILADELPHIA.

Cases of hydrocephalus exhibiting cerebellar symptoms, while not very rare, have been recorded in the literature with sufficient infrequency to warrant a report. The case to be reported is of still further interest on account of the probable cause of the cerebellar symptoms, which, if not unusual, has been infrequently described. The presence of a well-marked syringomyelia, which was not suspected during life owing to the absence of at least some of the characteristic clinical manifestations, is of additional interest.

History.—J. G., a boy, 8 years old, was admitted to the Howard Hospital, Jan. 8, 1908. The patient first applied to the dispensary of the Howard Hospital Nov. 2, 1905. The previous history was entirely negative. Ten days before his first visit he began to have headaches, associated with vomiting, which occurred before breakfast, although at other times during the day as well. He also complained of frontal headaches. The physical examination at that time showed that the head was enlarged. Examination of the eyes by Dr. William Campbell Posey was negative. Shortly after this there developed a spastic gait, but otherwise nothing of importance was noted until two years later, Nov. 29, 1907, when the child returned again to the clinic with a history of vomiting, attacks of frontal headache and general tremor. Station was poor, and the knee jerks were increased. There was a history of a general convulsion three years previously, and of several attacks, in which the patient fell, during the past year.

Examination.—He was admitted to the wards of the Howard Hospital on Jan. 8, 1908, when his condition was as follows: There was a coarse, irregular tremor of both hands on voluntary effort. The eyes were prominent, and the palpebral fissures unusually wide, showing the cornea above the pupil. The tongue was protruded straight, and there was no facial palsy. There was no stiffness of the neck, nor apparent tenderness in that region. There was a coarse, irregular tremor of both legs. The knee jerks were increased, and equally so. There was no ankle clonus, but the Babinski phenomenon was present on the left side. Kernig's sign was also present. The pain sense was generally preserved. Unfortunately a test for the other forms of sensation was not made, and the need of it was not specially indicated, for the patient did not give any history of burning himself without being conscious of it until afterward, a sign so characteristic of the early stages of syringomyelia. Moreover, there were no local atrophies to attract attention to the possibility of the existence of syringomyelia. The patient staggered when walking, and seemed to be weaker in the left leg than in the right. The sphincters of the bladder and rectum were incontinent.

Jan. 12, 1908, the headache was very severe; the head was retracted and the neck stiff. Any movement of the head increased the pain, which appeared to be general. At this time the knee jerks were slightly diminished, and there was a tendency to fall to the left, with the feet together and the eyes closed.

The patient died suddenly.

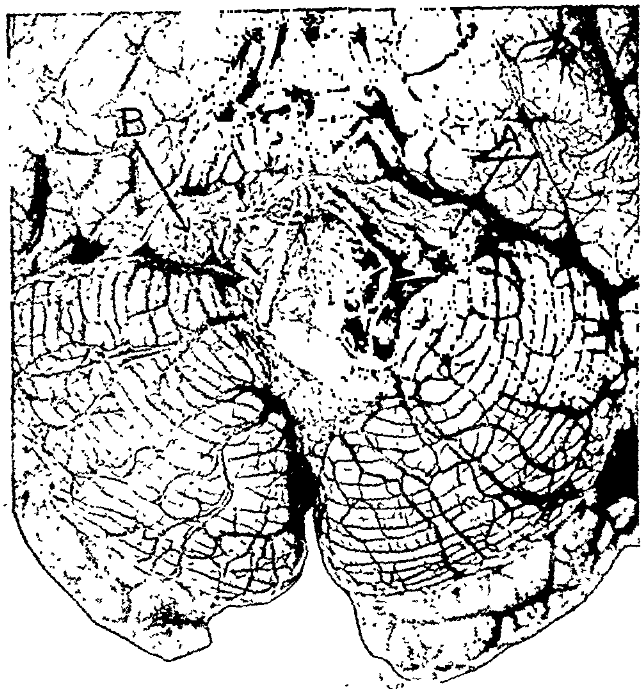

Fig. 1.—View of the hydrocephalic brain, showing two cysts, A and B.

Autopsy.—When the brain was removed, 6 to 8 ounces of cerebrospinal fluid escaped, and the very much distended brain collapsed to a certain extent. What appeared to be two cysts were observed at the cerebello-pontile angles (Fig. 1, A and B), the one on the left being the larger. These were distended with fluid, which escaped when the brain was removed.

The brain was placed in formalin, and the spinal cord in Müller's fluid. The entire cord was divided up into 23 approximately equal portions, and sections from half of these were stained by the Weigert method and by hematoxylin and acid fuchsin.

Cord: The spinal cord was the seat of a syringomyelia which extended from the eighth thoracic to about the second cervical segment.

At the second cervical segment there was a small cavity to the right of the central fissure. There was slight degeneration of the posterior columns, and the left crossed pyramidal tract.

In the fourth cervical segment the same condition was observed, and here also there was a slight dilatation of the central canal. In both posterior horns an area of loose tissue was observed in which were found several spider cells.

At the sixth cervical segment the central canal was very much distended. There was slight degeneration of the left crossed pyramidal tract. At this level there was a cavity in the right posterior horn, and in the wall of this cavity spider cells were seen.

---

[*] From the Howard Hospital and Department of Neurology and Laboratory of Neuropathology of the University of Pennsylvania.

[*] Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

In the eighth cervical segment the central canal was very much dilated and hour-glass shaped, occupying a large part of the posterior column. There was a large cavity in the right posterior horn and a small one in the left posterior horn. On the right side there was hemorrhage into the tissue of the wall of the cavity. The left crossed pyramidal tract was degenerated. At the second thoracic segment the central canal was large and round, and there was still a small cavity in the right posterior horn. Very slight degeneration of the left crossed pyramidal tract was observed. Both posterior horns were the seat of loose tissue, presenting the same characteristics as the levels above described.

In the third thoracic segment the central canal was irregular in shape, extending into the right posterior horn, and occupying a large part of the posterior columns on both sides of the median line. The degenerative process, present in the left horn, extended, at this level, into the anterior horn, and was less marked than in the levels above. In the fifth thoracic segment the right posterior horn was almost entirely destroyed by the cavity, and also part of the anterior horn, and the dilated central canal occupied the posterior part of the left horn.

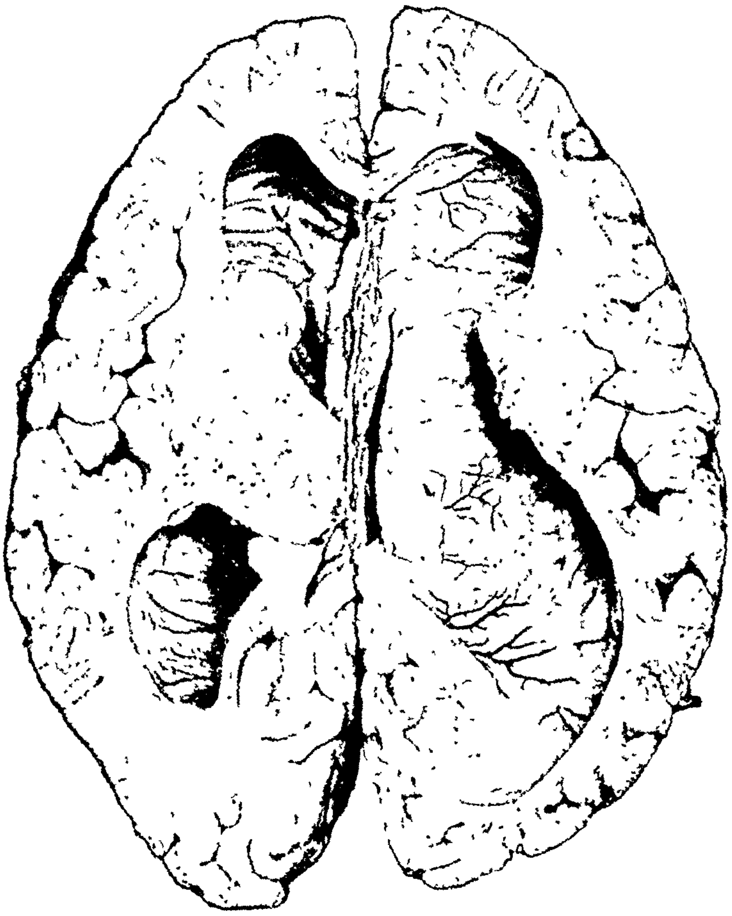

Fig. 2.—Cross section of the hydrocephalic brain showing distension of the lateral ventricles.

At the eighth thoracic segment there was a small cavity in the left posterior horn. At the ninth thoracic segment the cavity disappeared, and the central canal was not materially distended. There was no trace of degenerated tissue in the horns. At the segments below this level nothing abnormal was observed.

At the decussation the medulla appeared to be normal, except for some central loose tissue, probably of gliomatous nature. The ganglion cells of the anterior horns in the thoracic and lumber regions, stained by thionin, appeared to be normal.

Brain: Both lateral ventricles were very much distended (Fig. 2). The third ventricle was also greatly distended, pushing the tissues of the interpeduncular space downward. The aqueduct of Sylvius was very much distended, as well as the fourth ventricle (Fig. 3, C), especially the cerebellar portion.

The lateral processes of the fourth ventricle, and this is to be especially noted, were very much dilated (Fig. 3, A and B), and were continuous on each side with the cysts situated at the cerebello-pontile angles. That is to say, the portions of these recesses which came in contact with the subarachnoid space were not closed in as usual. The cerebrospinal fluid had apparently forced the arachnoid and pia out in such a way as to give the appearance of a cerebellar cyst on each side. The foramina of Magendie and Luschka could not be found.

Microscopically the ependyma of the lateral ventricles was not abnormal. The wall of the cyst on one side consisted of a pia-like structure, somewhat thicker, however, than the normal pia.

SUMMARY.

A boy of 8 presented the characteristic symptoms of cerebellar disease, slightly more marked on the left side. At autopsy a hydrocephalus was found, involving all the ventricles of the brain, distending the lateral recesses of the fourth ventricle and causing cysts at both cerebello-pontile angles. There was associated with this a syringomyelia which did not cause the characteristic symptoms during life.

It is not unusual for the symptoms of syringomyelia in children to be absent, even when well-marked cavity formation is present. This is illustrated in the case reported by Bullard and Thomas,[1] as well as by my own. Bullard and Thomas' patient, a boy 6½ years old, presented the symptoms of cerebellar lesion, and later there developed paraplegia and incontinence of urine and feces. The autopsy revealed the presence of hydrocephalus and syringomyelia, the latter not having been suspected during life.

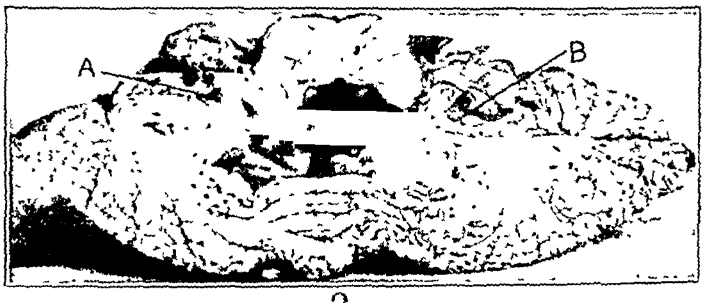

Fig. 3.—Showing, A and B, distended lateral recess of the fourth ventricle; C, distended fourth ventricle.

In cases of hydrocephalus the possible presence of syringomyelia should always be recognized, even when the usual symptoms of the latter are lacking.

The occurrence of cerebellar symptoms in cases of hydrocephalus is well known. Spiller,[2] in 1902, reported a case of hydrocephalus with symptoms suggesting cerebellar tumor and expressed the view that the possibility of internal hydrocephalus should always be borne in mind when tumor of this portion of the brain is suspected. He cited the cases of Bramwell,[3] in which the cerebellar symptoms were apparently due to hydrocephalus.

Since then Finkelburg[4] reported a case in which cerebellar symptoms were associated with moderate dilatation of all the ventricles. He stated that cerebellar gait occurred in chronic hydrocephalus, as well as with tumors of the central ganglia, as an early symptom. He believed that normal or lowered tendon reflexes are not against a chronic hydrocephalus. Circumscribed tenderness to pressure or blows on the cranium is found in chronic hydrocephalus, and has, therefore, no diagnostic value.

[3] Brain, 1899, xxii, 66
[4] Deutsche. Ztschr. f. Nervenheilk., 1905, No. 29, p. 135.

Schmidt[5] suggested a symptom which he claimed was of great diagnostic significance in deciding between hydrocephalus and cerebellar tumor. It consists of the appearance of vomiting and vertigo if the patient lies on the side opposite to a tumor. He reported two cases of cerebellar tumor in which the patients would constantly lie on the side of the tumor, and concluded from this that the pressure from the tumor on the aqueduct of Sylvius, if the patient would lie on the opposite side, caused closure of this aqueduct, and hence an increase in intracranial pressure. Finkelburg does not subscribe to this view, as he believed that these symptoms are found in other localized tumors of the brain. Schmidt believes that the Westphal phenomenon points to a tumor rather than to an idiopathic hydrocephalus.

The cause of cerebellar symptoms in hydrocephalus is difficult to explain in all cases. I believe that the increased intracranial pressure in my case, which was exerted more particularly on the cerebellum at the localities at which the cysts were found, explains the presence of these symptoms in this case and may have had something to do with the slight predominence of the symptoms on the left side, as the cyst on this side apparently had compressed the left lobe of the cerebellum. When the fourth ventricle, however, is not enlarged, and the intracranial pressure is not, therefore, high in the neighborhood of the cerebellum, this explanation is not sufficient. It must be due to another cause—probably the weight of the hydrocephalic brain on the cerebellum.

Descriptions of cysts, such as those in my case, have not appeared frequently in the literature. Scholz[6] divides cysts of the cerebellum into seven groups, i. e., (1) cysts similar to those in my case, which will be discussed later; (2) cysts accompanying new growths; (3) simple, or serous, cysts; (4) blood cysts, that is, apoplexies; (5) cysts from pressure or embolism; (6) dermoid cysts; (7) parasitic cysts. He quotes the case of Virchow, in which there was a cystic distension of the diverticulum of the fourth ventricle, and quotes a similar case by Clarus.

In Virchow's case[7] there was a partial dilatation of the fourth ventricle, which extended laterally, and sent out prolongations on each side, between the cord and the cerebellum, at which angle a cherry-sized cyst was found, compressing the facial nerve. He spoke of it as a hydrocele of the fourth ventricle.

This case undoubtedly is similar to mine, as was also the one described by v. Recklinghausen,[8] in which a bilateral cyst which communicated with the dilated fourth ventricle was found. An opening three millimeters in length was found behind the lateral angle of the floor of the fourth ventricle, leading directly into the sac on either side. The lateral ventricles were moderately distended and the ependyma was thickened. The wall of this cyst was somewhat thicker than the pia of the pons, which was continuous with the wall of the cyst.

J. Bland Sutton[9] cited the cases of Virchow and v. Recklinghausen, and calls attention to the origin of such cysts. He noted particularly that the cavity of the fourth ventricle is extended laterally by two tubular prolongations, or lateral recesses, which open into the subarachnoid space on each side. Key and Retzius were the first to call attention to this, and Sutton refers to the result of obstruction of these recesses, i. e., dilatations of the obstructed passages and the production of cysts.

Other than these brief reports, I am unable to find any reference to this condition in the literature. I believe, however, that these apparent cysts may readily be overlooked, as they are apt to collapse when the cerebrospinal fluid escapes at the time of the autopsy.

The cause of the cysts in my case I believe to be, probably, the closure of the foramina of Majendie and Luschka, which caused an accumulation of cerebrospinal fluid in the ventricles of the brain, and, as a result, the pia arachnoid covering the free borders of the lateral recesses of the fourth ventricle as well as the recesses themselves was distended by the excess of cerebrospinal fluid in the form of a cyst on each side.

The association of syringomyelia and hydrocephalus has been noted a number of times in the literature. Schlesinger[10] cites a number of such instances, and Hinsdale, in 150 cases of syringomyelia collected from the literature, found fifteen cases of hydrocephalus. Schlesinger looks on the significance of this process in syringomyelia as two-fold. He believes that it explains in some cases the general brain symptoms of paralysis of the cranial nerves, which are frequently attributed to syringomyelia; and that the existing hydrocephalus causes sudden death in not a few cases of syringomyelia by reason of an exacerbation of the process.

I wish to thank Dr. F. Jacobs for the opportunity of reporting this case.

1732 Pine Street.

ABSTRACT OF DISCUSSION.

Dr. Arthur W. Fairbanks, Boston: The occurrence of cerebellar symptoms in cases of hydrocephalus is not so very uncommon. Few such cases have, however, been reported. In such a case we have to consider whether such symptoms are the effect of the hydrocephalus or merely phenomena of a pathologic process, of which the hydrocephalus itself is merely one phenomenon. We are usually aided in deciding this point by the fact that in the first instance these cerebellar phenomena occur after the hydrocephalus has been existent some time, while in the second instance these phenomena either antedate the hydrocephalus or occur early in its course before its symptoms have become extremely marked. When secondary to hydrocephalus, cerebellar symptoms are due to the profound disturbances produced by the effect of greatly increased intracranial pressure on the functional activity of the cerebellum, the cerebello-pontile, and the cerebello-cerebral tracts, and the pons. This disturbance is in part due to effect of direct pressure, in part to circulatory disturbances secondary to the pressure, and ultimately to secondary degeneration of these tracts and cells, produced by long-continued high intracranial pressure. The direct pressure of hydrocephalus may so press down the cerebellum that its inferior surface may be found deeply indented by the edge of the foramen magnum, and occasionally actually deformed by such pressure. When not secondary but merely an associated symptom, this cerebellar disturbance may be due to the same condition that is responsible for the hydrocephalus. The most common cause of such occurrence is a new growth of the cerebellum or pons, which by virtue of its location causes the phenomena of cerebello-pontile disease, and by mechanical obstruction of the aqueduct of Sylvius, the foramen of Majendie or the foramina of Luschka, or the venous return flow through the veins of Galen, produces also hydrocephalus, with all its characteristic phenomena, in one and the same case.

Under such circumstances the cerebellar phenomena are usually the initial symptoms. We must remember, however, that cerebellar phenomena are not so conspicuous in the infant as in the older child, whereas, owing to the elasticity of the cranium, enlargement of the head becomes early conspicuous. Therefore, the early occurrence of cerebellar phenomena with enlarging head, in an infant, should always arouse more suspicion of actual cerebellar or pontile disease than in a child whose cranium is rigid and unyielding, and, therefore, the sooner subject to the secondary results of increasing intracranial pressure produced by hydrocephalus. I have in mind several such cases in very young children. In one child in particular, in whom the trouble began before the closure of the fontanelle, and from whose cranial cavity I afterward removed an enormous tumor of the vermiform process, the ultimate cause of the hydrocephalus was overlooked by two or three able men, the slight cerebellar symptoms not having been noticed by them. The presence of optic neuritis is of much help in these cases in infancy, and when present almost always points to tumor at this period of life. In older children, however, optic neuritis, while always a suspicious sign, is not quite so surely evidence of tumor, for it is sometimes seen in primary hydrocephalus, though rarely. Optic atrophy, on the other hand, is common enough, both in primary hydrocephalus and in the late stages of tumor, and is therefore of no differential value. Hydrocephalus may occur with cerebellar symptoms in cases of general cerebello-cerebral or cerebello-spinal sclerosis and atrophy, as in certain cases of cerebellar ataxia. Interesting in connection is the occurrence, in Dr. Rhein's case, of syringomyelia. In a number of instances of cerebellar ataxia, cavities and defects in the spinal cord have been reported. At a previous meeting of this Section I showed some lantern slides of this condition. These cases are often associated with a defect in the gray matter of the cord in the region of Clarke's column, where originate the fibers of the direct cerebellar tract. In several of these cases a hydrocephalus was also present.

ERYTHEMA FIGURATUM PERSTANS.*

GROVER WILLIAM WENDE, M.D.
Clinical Professor of Dermatology, University of Buffalo.
BUFFALO, N. Y.

In 1905 I read a paper before the American Dermatological Association at New York City on "Erythema Perstans Involving Circinate Lesions," with reports of two cases. In that paper all varieties of persistent erythema were included, some of which had been described previously as special diseases, each having its own pronounced characteristics. In this paper I have eliminated all save one variety. This variety presents persistent erythematous patches, which assume annular, marginate and gyrate forms, differing essentially from other varieties of erythema. A new case is now reported with a brief review of similar cases found in the literature.

REPORT OF A CASE.

History.—Emily R., aged 16, well developed, was referred to me in July, 1906, on account of a peculiar skin eruption, covering the entire body, which had existed since birth. Her mother, father, older sister and younger brother were all healthy and strong; there was no history of syphilis, congenital or otherwise. The mother was not aware of the existence of a like skin condition in any member of the family on either side. This condition of the skin made its appearance soon after birth, commencing as an unusually red and scaly condition of the skin, which was very sensitive, smarting and burning when bathing. It had no apparent relation to infantile eczema. This condition continued until the patient was about five years old, when the inflamed surface began to show oval, red patches, which, disappearing, left rings and irregular figures, save where the skin was normal. The subjective sensations now began to increase. At first the eruption appeared and disappeared rapidly, and there were intervals when for short periods the body was quite clear. During the last two years it had never been entirely free from the eruption. The skin manifestations had existed only occasionally on the palms of the hands and the soles of the feet, in the form of a red spot which never became scaly and disappeared in a few days. Five years ago most of the lesions on the body were subject to a discharge, which ran its course in a few days, ending in the formation of a crust, which soon fell off, leaving a dark pigmentation. This complication, probably, was independent of the original condition. The patient stated that, after sitting, the clothing would adhere to the skin, caused by a discharge from the affected parts, accompanied by pain and burning, probably due to pressure. This condition would arise during walking, undoubtedly the result of chafing. The face often showed lesions of the same character as those on the body. About six years ago the mother noticed the gradual disappearance of the facial redness. This condition was followed by an entirely different manifestation, beginning on the middle portion of the face, which was represented by a number of small, hard, yellow lesions the size of a pin-head to a pea, which gradually increased in dimensions and number until all portions of the face were invaded. The patient stated that her bowels had never been regular; that pain often followed eating. At night she was annoyed by skin sensations and was often disturbed by dreams.

Examination (August 1, 1906).—The body was in excellent nutrition; internal organs apparently normal; urine normal. At a slight elevation above the level of the skin were erythematous lesions, circinate, annular, gyrate or distinctly serpiginous, discrete or confluent, occupying the back and front of the thorax. The abdomen, the arms to the wrists and the legs to the ankles were covered with these lesions; hands and feet were free. The scalp showed only a slight desquamation. The size of the single efflorescences varied in diameter from a quarter of an inch, or less, to three inches. A small lesion was often found at the periphery of a larger one. The single lesions had a well-defined outline, generally oval or oblong. The ring lesions were covered with scales, except at the sharply defined, hyperemic, free margin. The center was pigmented, varying according to the size and age of the lesions, and the surface was covered with the finest scales. The smaller-sized lesions showed a similar condition; they were on the level of the normal skin, and were of a bright red color, which disappeared on pressure; scales were found only on lesions that had attained the size of a large pea. No scratch-marks were present.

Further Course.—The old efflorescences followed their regular course. At the same time a new lesion appeared on the chest, which was kept under observation, and quickly developed to a quarter of an inch in diameter. This lesion was bright red, with a darker border. Forty-eight hours later, its size had increased to three-quarters of an inch, without change, except at the center, where it began to disappear. The patient complained of local soreness. On the face there was present a different lesion, consisting of yellow, slightly translucent, symmetrical papules, varying in size from a millet-seed to a pea, raised well above the surface, generally isolated, but, in rare instances, appearing in clusters; these were most numerous about the nose, and extended gradually over the cheeks in the direction of the ears. This condition agreed in all essential points with the picture of adenoma sebaceum, and was so diagnosed.

Treatment (Feb. 1, 1898).—Arsenic, thyroid extract and other remedies were tried during the past eighteen months, without benefit. X-ray treatment was kept up for about eight months, without favorable effect. The adenoma sebaceum was removed by electrolysis, with permanent relief. The patient, an intelligent girl, wrote me under the above date: "Th condition of the skin is just the same as it was when I consulted you, not showing the slightest degree of improvement." In June, 1907, she suffered from an attack of colitis, which so affected her general condition that she was obliged to stay out of school until the first of February, 1908.

---

* Read in the Section on Cutaneous Medicine and Surgery of the American Medical Association, at the Fifty-ninth Annual Session, held in Chicago, June, 1908.

Histologic Examination.—For this a fragment of one of the circles was chosen. The excised lesion was red and smooth. The tissue was hardened in alcohol, cut in paraffin, and the usual stains employed. In the pars papillaris of the corium the most noticeable change was a well-marked infiltration of round plasma and connective tissue cells, especially located around the blood-vessels. There was a dilatation of the superficial capillaries and edema of the fibrous bundles, causing the almost complete disappearance of the papillary body. The infiltration extended to the subcutaneous tissue, without sharp limitation. The sebaceous and sweat glands appeared normal, although surrounded by round cell infiltration. The stratum Malpighii above the cellular infiltration showed no special changes, except that the basal layer was broken by the underlying edema with separation of the prickle cells, which were swollen in places; mitosis was also observed. Few leucocytes were found. The granular layer appeared almost normal. The stratum corneum showed a deficiency in cornification, although the scaliness must have been induced by the underlying edema. The cells adhered instead of normally desquamating. The clinical diagnosis of the face lesions as adenoma sebaceum was verified by microscopic examination. The lesions were entirely made up of sebaceous gland tissue, agreeing in the arrangement of cells with the normal gland; in the glandular arrangement, bi-, tri-, and even quadri-lobulation could be demonstrated; ducts could also be traced to the hair follicles.

General Condition.—There was nothing in the patient's general condition suggestive of a cause, except that intestinal disturbance was nearly always present. One can only speculate as to the possible relation of the two different skin conditions; structurally there was a distinct difference. It may be that both were due to errors of development, involving not alone the sebaceous glands but the whole skin.

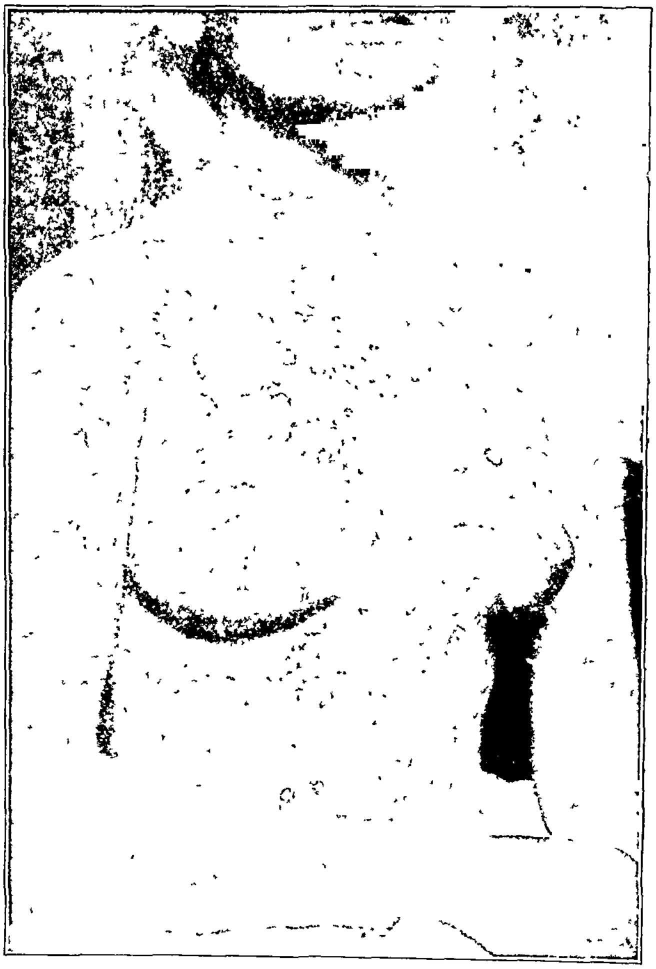
HISTORICAL CONSIDERATIONS.

Before presenting conclusions relating to this subject, I shall give an abstract of a number of cases, chiefly recorded in the English and American literature, as follows:

Bazin, Paris, in a text-book published in 1862, presented the view that certain rare forms of erythema may be of long duration, differing in configuration and lasting for months and years.

The two principal French dermatologic journals are comparatively free from descriptions of unusual forms of erythema resembling the one under consideration. There are many instances recorded in the *British Journal of Dermatology* of a variety of erythema perstans of the face and of the back of the hands, and often showing ring-shaped lesions in the regions usually invaded by lupus erythematosus. But I do not associate it with the class under discussion. Whether such cases in general represent an early stage of lupus erythematosus, or are distinct, it is difficult to determine, since certain of these cases are recorded as beginning with erythema perstans and ending as lupus erythematosus. For the purpose of close comparison, reference is made only to cases presenting a striking resemblance to my own, or to others more or less closely allied to it.

Fox[1] reports two cases of erythema gyratum perstans in the older members of a family who had the disease from early childhood. The condition began as papules, accompanied by intense itching, quickly extending, so that in a few hours a circular red area was noted, covered with scales, or, at times only, fringed at the border with conspicuous desquamation. The redness of the center soon subsided. The erythematous border was narrow and only slightly raised. The rings enlarged to the size of the palm of the hand, coalescing with other similar ones and forming gyrate, festooned figures. Both patients had recurrent outbreaks of this condition without fever. The skin was never absolutely free between attacks; usually about three severe outbreaks, with many minor ones, occurred in the course of a year. Fox associates the outbreaks with changes in temperature, as the disease was less intense during the winter. He had one patient under observation until he arrived at the age of 29, and considered the condition as unique. He stated that it reminded him of erythema multiforme, but did not really belong to that class. Various forms of treatment were used without favorable result.



Dr Wende's case of erythema figuratum perstans.

Lustgarten, under the title of "Erythema Papulosum vel Urticatum, Figuratum, Perstans et Chronicum,"[2] presented a case before the New York Dermatological Society. The patient was 21, and had been kicked by a horse fifty days previous to the oncoming of an eruption ushered in by intestinal disturbances. It first appeared on his body and gradually extended to the extremities. The lesions were annular and gyrated, with elevated borders, associated with pigmented skin. Weeks and months before they disappeared new patches were constantly added. Lustgarten considered the condition as a reflex neurosis of traumatic origin.

---

[1] International Atlas of Rare Skin Diseases, 1891, Part V.

[2] Jour. Cutan Dis, vol. xi, p 110.

Finney,[3] under the title, "erythema marginatum perstans," records a case in a patient aged 21, whose general health was good, with the exception of indigestion, presenting an erythematous eruption made up of pinkish-red, elevated lesions, linear, curved, segmentary or erythematous areas occupying the unexposed portions of the body. The raised areas were pigmented and covered by the finest possible scales. The ring forms were non-scaly. The glands were enlarged. The disease varied according to temperature, being especially affected by cold. The eruption was itchy. The inception of the disease was accompanied by constitutional symptoms; during the further course of the skin manifestations there were no febrile disturbances. Finney regarded the case as a variety of erythema multiforme.

Arning[4] reported a case of erythema perstans pseudoleprosum which undoubtedly belongs to this class, although it involved a much slower process. The patient was a young woman who suffered from functional nervous conditions. The slowness of the development was remarkable, the lesions attaining only the size of a dollar in four months, being most pronounced at the border. The greater part of the anterior surface of the tibia was covered with a coalescent lesion. Its duration was over eight months. The patches also developed on other parts of the body. Arning said that the appearance of the lesion corresponded to the incipient stage of leprosy, but that the latter disease could be absolutely excluded.

Wende[5] reported two cases of erythema perstans presenting circinate lesions.

Case 1.—This was that of a blacksmith, aged 28, who enjoyed the best of health. The course of the disease covered four and a half years. The eruption varied, at times covering the entire body and at other times completely disappearing. Four fresh outbreaks occurred during a single year. The lesions varied in size from the diameter of a pea to three inches, and were of a violet-red color. In the larger lesions the edges were well formed and were made up of rings, or segments, resulting in gyrate or serpiginous figures of varying sizes, the largest reaching a diameter of four inches. The surface was faintly pigmented, rough, and covered with scales. The only remedy that appeared to influence the eruption was chrysarobin, externally applied, but the lesions promptly returned on its discontinuance.

Case 2.—The patient in this case was aged 38; the duration of the disease four months. The lesion began as a papule which sometimes extended peripherally, forming a patch the center of which gradually faded, leaving a circular or gyrate outline, varying in size from that of a papule to about six inches in diameter. The gyrate lesions were elevated at the border, slightly uneven, varying in color from a livid to a bright red, and gradually extending until they covered the greater portion of the body. The edge of the areas developed slowly. Itching was present at times, occasionally intense and limited to certain portions of the body. At times evanescent lesions, resembling urticaria, appeared. Treatment proved of little value. Histopathologically there was superficial inflammation, showing, in particular, dilatation of blood vessels, infiltration of cells and edema.

In a discussion following the report of Wende's cases before the American Dermatological Association, Fordyce reported two similar cases, illustrated by stereopticon views and photographs. One of the patients showed lesions limited to the back; in the other they were confined to the arms and thighs; the duration in one case was six months, in the other a year. Fordyce regarded the condition as dependent on a vasomotor paresis.

In the same discussion Schamberg showed a photograph of a case of four months' duration in a young man, described as persistent annular erythema of the thighs and arms, which had responded to treatment by chrysarobin.

Winfield also described a case which he considered erythema multiforme perstans,[6] showing erythematous patches varying in size, the largest several inches in diameter, and distinctly annular and raised. There were very few circinate lesions. The smaller ones were discoid.

Corlett, at the thirteenth annual meeting of the American Dermatological Association, June, 1906, showed a patient whose case he considered as one of erythema figuratum perstans. This case was remarkable, possessing many features characteristic of the disease under discussion. The patient was a girl, 21 years old, with peculiar linear and gyrate figures covering almost the entire body, which would fade and then recur. A feature in Corlett's case not observed in others was the occurrence of rings within rings, following the lines of evolution established by the first. The only other case showing the same peculiarity is that described by Adamson.

Adamson[7] mentions a case of ringed eruption before the Dermatological Society of London, that of a boy aged 5, otherwise in good health, and who had been under observation for nine months. The eruption consisted of symmetrical rings on the outside of the arms and thighs, from half an inch to three inches in diameter, which faded, then became more pronounced, and at times entirely disappeared. The rings began as red, slightly-raised, erythematous spots, which extended peripherally, fading in the center so that circinate bands were formed. "The outer half of the band—the advancing margin—remained smooth, red and slightly raised, while the inner half was scaly and desquamating." Adamson considered the eruption as a form of erythema multiforme exudativum.

In the discussion following Adamson's report Fox referred to his two well-known typical cases[8] occurring in a single family.

Adamson[9] has recorded another case of circinate eruption which had been diagnosed in India as "Dhobie itch." The disease had appeared nine years previously while the patient was acting as an army captain in India. Adamson described the condition as showing circinate lesions, varying in diameter from two to eight inches, with an outer advancing margin, slightly raised, pinkish, smooth and free from scales. Many of the lesions consisted of concentric rings. Itching was a feature. Ringworm was excluded. Adamson observed that there were many features which corresponded to an example of persistent circinate erythema occurring in a boy of 5, which he showed before the dermatologic section of the Royal Society of Medicine, and again at a subsequent meeting, fourteen months later, before the same society.[10] The doctor compared the case that occurred in his patient (the boy of 5) with the two cases recorded by Fox and the one reported by himself[9] relating to the army captain from India. The present case was under his observation for twelve months. The eruption disappeared either spontaneously or under the influence of salicin.

CONCLUSIONS.

1. Such cases as are considered in this paper are few in number, but are sufficiently characteristic to be described as a distinct variety under the title of "erythema figuratum perstans." Some of the cases possess anomalous features, suggesting a type of erythema multiforme, yet not sufficiently distinctive to place them in that group.

2. The disease under consideration begins with scattered and isolated papules, which tend to fade at the center while extending peripherally, thus forming circinate erythematous outlines. The outer half of the advancing margin is smooth and slightly raised, the inner edge scaly and desquamating—a marked feature. The surface over which the disease has traveled is sometimes slightly scaly and pigmented. The larger lesions vary in size from a 25-cent piece to the palm of the hand—occasionally larger. The rings assume circinate, annular, discrete, confluent, gyrate or zigzag forms. In certain instances the lesions, whether evanescent or of long duration, do not develop the ring form. Two observations have been made in which the lesions formed within the area occupied by the disease followed the lines of evolution established by the first. Subjective sensations may or may not be felt.

3. In these cases, clinically considered, the erythema presents a peculiar type, different from any other form. This difference is further confirmed by the inflammatory character of the lesion, with an absence of pronounced infiltration in the fresh foci. The arrangement of the skin lesions constitutes the most important clinical feature.

4. The rate of the development of the lesions of erythema figuratum perstans varies widely. In some instances the ring lesions extend as much as a half-inch in a couple of hours, while in others the same growth requires an indefinite period. Exacerbations vary with the case, sometimes occurring three or four times a year, or oftener. As a rule, the body does not entirely clear up during the intervals. The outbreaks are in some cases said to be influenced by change in temperature.

5. There is no special sex or age predisposition. The disease asserts itself in earliest childhood as well as later in life. In rare instances it begins at birth and may be regarded as congenital. The patients are generally in good health; in a few instances the disease is reported to begin with constitutional disturbances. The etiology of this peculiar skin affection is meager and unsatisfactory and necessitates a careful study from a purely medical standpoint. It is fair to assume that the manifestations in the alimentary tract indicate the presence of an irritant circulating in the blood which, acting on the cutaneous vessels, produces this peculiar result.

6. In erythema multiforme there are usually more pronounced constitutional disturbances. The concentric rings in erythema multiforme show variegated colors and have special clinical varieties, such as erythema iris, erythema tuberculatum and erythema nodosum. The annular variety of erythema multiforme presents an entirely different appearance, is more acute, more deeply infiltrated, and its involution and evolution are entirely different from erythema figuratum perstans. The distribution of erythema multiforme may be general or local, confined even to the mucous membrane of the eye, tongue or mouth. It is often limited to one or two regions, but, whatever parts are involved, the backs of the hands seldom escape, therein differing from the persistent form. The duration of erythema multiforme is from two to four weeks, although it may last much longer.

7. Only a few cases have been studied microscopically. The pathology is that of a superficial inflammation, characterized by dilatation of blood vessels, edema and infiltration of round, plasma and connective tissue cells, especially about the blood vessels, sebaceous and sweat glands. The epidermis shows edema and defect in the process of cornification.

8. No method of treatment has proved permanently curative. The eruption can often be removed by external applications of chrysarobin, but its return is certain. The *x*-ray has been used in one case over a long period without benefit. Internal remedies have proved useless.

ABSTRACT OF DISCUSSION.

Dr. Frank H. Montgomery, Chicago: The grouping of erythema that Dr. Wende has given us in his paper is based on special clinical features. From an etiologic standpoint, however, I question whether such sharp lines can be drawn between these forms of erythema, on one side, and erythema multiforme and lupus erythematosus, on the other side. In connection with this group of eruptions, we have to consider both the toxin and the tissues. We have, for example, the toxin of an acute intestinal catarrh, acting for short periods of time on tissues of ordinary or special susceptibility, and producing erythema multiforme. Then, again, we have a more persistent action of less intense toxin and producing a more persistent erythema. Would Dr. Wende attempt to separate these forms absolutely on etiologic and pathologic grounds, or is it not at present a very convenient and desirable clinical group?

Dr. Grover W. Wende, Buffalo: I should be inclined to separate the condition described in my paper from erythema multiforme and to consider it as distinct. It is true that the little we know about the etiology corresponds with that of erythema multiforme; nevertheless the same cause or causes may be taken into consideration with many dermatoses that depend on intestinal derangements. The clinical picture is entirely different, not alone in the evolution and involution of the lesions, but also as to the locality that is usually invaded. In erythema multiforme the backs of the hands and the face are the parts usually invaded. In the cases under consideration there was no special tendency for the disease to limit itself to these localities. It is true that there is a persistent form of erythema multiforme, but it is usually limited to the locations mentioned, and it may be, as often considered, the forerunner of lupus erythematosus.

VOLUNTARY UNILATERAL NYSTAGMUS. WITH REPORT OF A CASE.*

WALTER L. PYLE, A.M., M.D.
PHILADELPHIA.

The case herewith recorded is one of extreme interest, in that it exhibits a combination of the rare anomalies of unilateral and voluntary nystagmus. Either condition alone is sufficiently infrequent to be worthy of extended report.

Patient.—A young woman, aged 22, in excellent physical condition, and of average size and proportions, consulted me for relief from frontal and sick headaches, which had not responded to extensive general medical and neurologic treatment.

Examination.—There was well-marked, chronic catarrhal conjunctivitis in the upper and lower eyelids of both eyes, with a troublesome edema of the left eyelids. There was also complaint of pain in the left eye, particularly in close work. The patient had never worn glasses, and until the last ten or twelve months had experienced no inconvenience in her visual labors. In fact, she had been remarkably free from ocular disturbances. There had never been any association of ocular affection with her headaches. It was only when other means had been exhausted that as a last resort she was advised to apply for ocular examination. Under homatropin cycloplegia, I found a small amount of compound hyperopic astigmatism at horizontal axes, equal in amount in both eyes. Both with and without optical correction, the visual acuity was normal. There was no heterophoria or other disturbance of the ocular musculature. In the course of examination, I noted a sudden unilateral convergence of the left eye, with subsequent rapid oscillation for about 30 seconds. In a few minutes this recurred, which circumstance determined me to make guarded inquiry into the phenomenon. I soon found that the oscillations could be inaugurated voluntarily and as promptly checked. Although the patient disclaimed any knowledge of her ability to effect these maneuvers, she stated that she had never, for purposes of exhibition or self-experiment, produced the nystagmus. However, she exhibited no surprise at my demonstration of her extraordinary ability in this direction, which would lead to the natural inference that she was fully conscious of her power. Repeated experiments failed to show any such control of the right eye. The family history was good, and there could be obtained no records of any noteworthy ocular affection in two generations, with particular reference to any disturbance of the extraocular muscles. She could not remember any case of strabismus in the family.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Treatment.—The constant use of proper glasses was followed by prompt and complete relief from all the asthenopic reflex symptoms, and when the patient left me, a month later, she was quite satisfied with her ophthalmic experience.

Remarks.—A year later I directed a letter to the address that she had given me, but received no reply, and hence am not able to record the after-history. I am in hopes of discovering her whereabouts, however, and in such case will publish a supplementary note to these observations. During her last visit, at intervals of about 5 minutes, she three times gave a demonstration of her extraordinary faculty and seemed to effect the oscillations with as much ease as before. The only requisite seemed to be the act of convergence, which, however, did not necessarily have to be extreme. The oscillations could be easily produced while the eyes were fixed on type at the ordinary reading distance.

UNILATERAL NYSTAGMUS.

Although unilateral nystagmus is of rare occurrence, a number of cases are recorded in modern ophthalmic literature. Alexander Duane,[1] in a discussion before the New York Academy of Medicine, March 20, 1905, classifies the anomalous types of nystagmus under the following headings:

1. *Disjunctive Nystagmus.*—The two eyes move, not in parallel directions, but alternately and away from each other. The movements are symmetrical and equal in the two eyes.

2. *Dissociated Nystagmus.*—The movements of the two eyes are unsymmetrical and unrelated, one either moving much faster and further than the other, or moving in a totally different way.

3. *Unilateral Nystagmus.*—He regards this as a variety of the second form. He also refers to circumduction nystagmus as an extremely rare form of the affection.

In common with Neustätter, Schapringer, Spicer and others, Duane believes that most cases of unilateral nystagmus are really of the bilateral type, the movement of the supposedly quiet eye being very minute, and thus escaping detection. In this connection it should be noted that in many instances the lesser forms of nystagmus are not made frankly manifest until an ophthalmoscopic examination is attempted, or the eyes are tested in extreme rotations.

Alfred Graefe[2] mentions a curious case of vertical nystagmus in one eye and horizontal nystagmus in the other, which at first sight might have been considered unilateral or alternating nystagmus. He ingeniously demonstrated the type of movements by the shape of the corneal images of a candle flame—in the horizontal form the image was broadened; in the rotary form, it was enlarged in all directions.

Duane states, however, that he has seen but two undoubted cases of unilateral nystagmus. He also records one case of unilateral rotary nystagmus, in which, however, there later developed bilateral movements. Simon records one case in which at first the nystagmus was unilateral and mixed (vertical and rotary), but subsequently became bilateral and horizontal. It is of interest to note that a nystagmus originally bilateral may become unilateral. According to Schapringer, in spasmus nutans the nystagmus may disappear in one eye only. Again, according to Simon, bilateral nystagmus due to bilateral corneal opacities may disappear from the eye which clears first. He reports two cases in which infantile unilateral nystagmus was caused by unilateral corneal opacities. In the case under discussion, the nystagmus was originally bilateral and disappeared, first in one eye, and then in the other as the respective cornea cleared. It is worthy of mention, however, that nystagmus seldom occurs in cases of unilateral amblyopia, strabismus being the usual consequent disturbance of the musculature. Heimann mentions the occurrence of unilateral nystagmus in an amblyopic strabismic eye; but, according to Duane, such occurrence should be recorded as an acquired optical nystagmus rather than one infantile in origin. According to A. Graefe, in some of the cases of nystagmus, infantile in origin, without demonstrable causative ocular lesion, the oscillation may be attributed to a congenital retinal hemorrhage, which subsequently cleared.

Cases of unilateral nystagmus have been reported by Neustätter, Schapringer, Krause, Heiman, Spicer, Duane, von Reuss, Eversbusch, Bouchaud, Norrie, R. Sachs, Nagle, Oppenheimer, Weber, Schwarz, Simon, Nettleship, Soelberg Wells, Fuchs, Noyes, and A. Graefe. Of 52 cases collected by Duane, 34 were vertical, 11 horizontal, 5 rotary, and 2 mixed. In none of the cases reported, however, was the condition of voluntary nystagmus mentioned.

Duane points out three varieties of tremor of ocular movements: 1. Searching movements. 2. Pseudonystagmus, or jerking movements, which he says are not infrequently unilateral, particularly if the affected eye has the relatively weaker muscles. 3. True nystagmus, in which the eyes make a series of very regular, short, quick oscillations about a central point.

Unilateral nystagmus, he says, may be associated in early life with spasmus nutans, or unilateral opacity of the media. In later life, it may arise from unilateral amblyopia and unilateral opacity of the media, unilateral astigmatism, and nervous diseases (especially multiple sclerosis). From his observations he deduces that unilateral nystagmus differs in no essential way from bilateral nystagmus, but represents simply a form of the latter.

---

[1] New York State Jour. of Med., 1905, v. 245.

[2] Graefe und Saemisch Handbuch, vi. 1.

Nettleship[3] mentions three brothers (children), all of whom exhibited unilateral nystagmus; two were subject to "fits" and were strabismic. He reports another case of unilateral nystagmus in an infant, with rhythmic movements of the head and corresponding arm. He observes that this type of nystagmus, and associated with rhythmic movements of the head and arm, is not exceedingly rare; and also that this association of epileptic convulsions and other important nervous affections is not uncommon.

Zehender[4] also describes the case of a child with unilateral nystagmus.

Related to corneal opacities as a cause of nystagmus may be mentioned astigmatism. Stevens[5] reports five cases of functional nystagmus, or, as he prefers to call it, talantropia (an oscillating), in one family; a brother, two sisters and two young cousins (a boy and girl), in all of whom there was a high degree of astigmatism. Although no such case is recorded, it is quite possible for unilateral nystagmus to be associated with high unilateral astigmatism, and I have seen, personally, a nystagmic patient in whom the oscillations in the highly astigmatic eye were much more marked than in its less ametropic fellow.

Bernheimer[6] reports a case of a hypermetropic patient in which nystagmus was produced after prolonged close work, and disappeared after the use of proper correcting lenses. I have seen similar relief follow the full correction of astigmatism in at least a half-dozen such cases. It is my custom in all cases of purely functional nystagmus, and even in cases in which there are pronounced intraocular changes, to prescribe for constant use full correcting lenses, after most careful subjective and objective examination of refractive conditions, when necessary, under complete cycloplegia. Often there follows almost immediate subsidence in the rapidity and extent of the oscillations. Even in cases of nystagmus associated with grave cerebrospinal disease, I believe such procedure advisable, but, of course, with much less hope for noticeable improvement.

VOLUNTARY NYSTAGMUS.

Inasmuch as the term nystagmus signifies an involuntary oscillation of the eyeball, it is perhaps awkward or at least illogical phraseology to speak of voluntary nystagmus. J. W. Smith[7] has suggested as a better name for this condition ophthalmodonesis, which he defines as a voluntary tremulous or oscillating movement of the eyeballs.

Mention of voluntary nystagmus is exceedingly rare in ophthalmic or neurologic literature, and in most of the related text-books little or no mention of this condition is made. Graefe believed that voluntary nystagmus could only occur in persons who were formerly the subjects of an involuntary nystagmus which had disappeared. However, I have been able to find sufficiently accurate and complete reports of cases of pure voluntary nystagmus by Benson, Lawson, J. W. Smith, W. E. Gamble, Noyes, Williams, Dodd, A. E. Davis, J. E. Colburn, Grimsdale, Ernest Clarke, and Fuchs.

A. H. Benson[8] records a case in a young woman of 24, who could cause oscillation of her eyeballs at will. The motion was very rapid, but the excursions were short. It is noted that the nystagmus was always bilateral and at no time were there involuntary oscillations. The patient was slightly hyperopic. George Lawson[9] mentions having examined a man who all his life had been able to control his eyeballs at will. In this as in the preceding case the motion was so rapid that the margins of the cornea could not be continuously defined. As in the previous case the voluntary nystagmus was always bilateral. Lawson refers to another case observed by him in the person of a former house surgeon of the Royal London Ophthalmologic Hospital. In this instance, the lateral movements were not so rapid and it was necessary for the patient to converge his eyes before the oscillation could be started. The movements were invariably bilateral and under complete volition. In 1882, J. A. Campbell[10] recorded the case of a presbyopic woman who could vibrate both eyes horizontally at will. This seems to be the first American case reported.

Ernest Clarke[11] records an unusual case of nystagmus, which, while not voluntary, is of sufficient interest for mention here. The patient was a youth of 19 who had been apprenticed to a jeweler three years before. While working at his trade, while the eyes were fixed for any object at any distance, the view was cut off from either eye by the interposition of an opaque object, horizontal nystagmus occurred in both, the oscillation being slow and jerky when the right eye was occluded and rapid and more regular when the left eye was blocked. It is also noted that extreme movement in all directions would produce nystagmus. H. B. Grimsdale[12] reported four cases in which occlusion of either eye produced nystagmus, which immediately subsided on the restoration of the binocular vision.

These cases are analogous to those reported in a paper on "Acquired Nystagmus in Occupations Other Than Coal Mining," by Simeon Snell.[13] This author has written extensively on miners' nystagmus, which he attributes to prolonged natural upward rotation rather than to insufficient illumination. In the paper under discussion he mentions the classical and interesting biographic note of Michael Angelo set forth by Condivi, which was corroborated by Vasari, the contemporaneous biographer of the celebrated decorative painter. It is authoritatively stated that during his lifetime Michael Angelo was so affected by his strained attitude in gazing up at the vaults in the Sistine Chapel, in which for many months he was engaged in the work of decorating with frescoes, that he lost for some time the power to read except when he elevated the paper above his head and raised his eyes. Further, it is stated that Michael Angelo wrote a sonnet describing the constrained attitude in which he was compelled to work and its consequent disagreeable sequels—translation of which has been made by John Addington Symonds. Symonds remarks that the autograph of this manuscript included a humorous little caricature on the margin, showing a man, with protruded stomach and head bent back, using his brush on the surface high above him. He also mentions that as far back as 1874 Nieden recorded a case of acquired nystagmus "in a plank cutter," a workman who, in standing under the tree, observes very exactly a line marked for cutting, while keeping the eyes in a strained condition and upward direction—work very similar to that done by a bottom-sawyer in England. In a letter to Snell, Nieden remarks that, although he has made investigation in many cases of painters and ceiling decorators, he has not been able to find a case of regular nystagmus, although the symptoms of muscular asthenopia were often complained of. In his paper Snell has personally collected 21 cases of acquired nystagmus occurring in different occupations, comprising 6 compositors, 2 metal rollers, a plate layer, a plank cutter, a saw maker, a sanitary tube maker, a fitter and iron founder, a worker in a "cage," 2 employés in a glass factory, a youth engaged in a confectionery warehouse, a man employed at the screens at the surface of a coal mine, a tool sharpener, and a custodian of a harness room. In all these cases the occupations necessitated unusual strain on the elevator muscles of the eyeballs, causing at first a weariness and later oscillating movements. The nystagmus in these cases, however, was less intense than in the generality of cases met in miners. Snell also refers to the headaches of the visitors of the large art galleries and sightseers in churches and large public buildings, and, although he does not report distinct nystagmus, muscular asthenopia and instability were frequently noted.

In 1896 Gamble[14] reported to the Chicago Ophthalmologic Society a case of voluntary lateral nystagmus in a German-American medical student of 24. While attending high school at about the age of 15, he first discovered that he could produce at will lateral nystagmus, which, however, was never involuntary. No difficulty was ever experienced in starting the oscillations, but they could only be continued for less than a minute. The patient was not able to produce unilateral oscillations. The nystagmus was most pronounced when the eyes were fixed on an object six or eight feet distant, directly in front, but even in making the lateral excursion it could be continued with much less rapidity. Gamble notes that the rapidity of the oscillations were as great as he had ever seen in any case of involuntary nystagmus. It was more pronounced in daylight than under artificial light. The patient had never been ill and did not suffer from headaches or eyestrain, notwithstanding the fact that he had always been a student and teacher. His refraction was:

R. + Sph. 2.00 + Cyl. 0.50, ax. 180° = 20/20.
L. + Sph. 0.25 = 20/20 +.

The media were clear, the fundus healthy, the field of vision full, and the color sense normal. The patient had never worked in the mines nor lived in a mountainous country. He had never had writers' palsy, or other profound nervous manifestation. Gamble states that the one other case similar to his that he had seen reported was that by Noyes,[15] in a patient who had acquired the oscillations after having been confined to his room for several weeks suffering with ocular disease. Noyes remarks that in his experience this case was unique. In his text-book Fuchs mentions rare instances of persons who could produce nystagmus voluntarily. Gamble refers to Noyes' case, which he had seen through the courtesy of the elder Williams, of Boston.

H. W. Dodd[16] reports a case of bilateral voluntary nystagmus in a man, an organist, of 23. The patient could produce at will conjugate lateral movements of the eyeballs. When he desired to demonstrate this faculty he would fix his head, look forward, open widely the eyelids, and, as he expressed it, "simply wish" to cause the oscillation. No great effort was entailed and only occasionally was there resultant vertigo or headache. The oscillations could be produced while looking up, down or laterally, either at a distant object or at close range, and also while under the influence of a cycloplegic. The objects looked at moved from right to left, or *vice versa,* and it may be mentioned here that only in voluntary oscillation are subjective disturbances of vision, nausea, vertigo, etc., seen. In all cases of voluntary nystagmus the oscillations can only be continued over a short period, usually in one minute. Dodd's patient possessed the remarkable faculty of being able to converge vigorously, while continuing the oscillations. The power of voluntary nystagmus was first observed at the age of 9. The family history was negative in regard to nervous or mental diseases, and the patient was particularly exempt from any nervous affection. Vision and refraction were practically normal, although there was a patch of chorioretinal degeneration in the right eye, which was of eight years' standing.

Possibly the most complete published record of a case of voluntary nystagmus is that by J. W. Smith.[7] The patient was a male student of 21 of French, Huguenot and English parentage. The family history was good, and the only remarkable ocular affection was noted in a sister of 17, who exhibited apparent convergent strabismus of the left eye in near vision, but whose eyes were in normal balance when directed at distant objects. Beyond a slight inflammation of the eyes at the age of 7 or 8, which speedily subsided under the instillation of a common eye lotion, there was no history of ocular disturbance in the patient. There was absolutely volitional rapid oscillations of both eyes simultaneously in the lateral direction or in the horizontal plane. The oscillations could be started and stopped at the patient's will. A careful subjective examination of the eyeball showed no marked disturbances of refraction, muscle balance, accommodation, fields of vision, color sense, or visual acuity. Ophthalmoscopic examination was negative. There was no malformation of the globe or orbit. The innervation of both the intrinsic and extrinsic ocular muscles appeared perfect, and the patient experienced no asthenopic symptoms, even after long-continued, close vision. The eyes oscillated only in the horizontal plane, but the motions could be produced not only in the primary position, but in the secondary positions, such as extreme convergence, extreme divergence of either eye, and looking upward and downward. The oscillations could be continued during the entire excursion of the globes (circumduction). Oscillations could be produced when the lids were closed and also when the patient looked through a 20° prism placed before either eye, with its base in any position.

It may be remarked that it is generally accepted that visual sensation influences all the various movements of the eyeball; that is, the efferent motor volitional impulses are originated or are preceded by afferent visual influences. In comment on this statement, J. W. Smith with good reason remarks it is certainly apparent in his case that the patient did not depend on visual sensation for the movements of his eyeballs, for he could produce the movements without looking out or *for an object*, either real or imaginary, and, indeed, could produce the movements with his eyelids closed, or in the dark, or without fixing the object. Likewise he could produce the movements of his eyeballs whether he fixed on an object at near range or in the distance. This would seem to show the independence or volitional character of the movements, and thus by elimination, "visual sensations may be excluded as a factor or elements in the causation of the ocular movements in this particular case. Again, if this be true, efferent motor volitional impulses are not wholly dependent on those afferent." Smith believes that the oscillations in his case were dependent on efferent impulses affecting the nervous centers in control of the ocular musculature, or, perhaps, the co-ordinating centers in the corpora quadrigemina, in which case he believes that "if they are not due to visual impulses they must be connected with the kinesthetic or psychomotor cerebral cortex."

[14] The Jour. A. M. A., 1899, xxxii, 483.
[15] Diseases of the Eye, 1890.
[16] Trans. Ophth. Soc., U. K., 1901, xxi, 244.

The longest period during which Smith observed the movements was thirty-five seconds. The patient stated that in producing the nystagmus there was a sensation of slight pressure on each eyeball, pushing or pressing it forward. Ordinarily, during the production of the oscillation, the palpebral fissure was abnormally wide and the upper lids a trifle unsteady, causing noticeable exophthalmos. There was never observed any change in the pupil during the oscillations. Objects viewed while the eyes were vibrating had a simultaneous movement. At distance, objects appeared to be constantly changing their position, and at close range they doubled and blurred. When the patient vibrated his eyeballs and fixed the object, it seemed double and the images appeared to approach and recede. The oscillations could be produced in daylight or in darkness and in the presence of artificial light, with equal energy and rapidity. The amplitude of the vibration was about one millimeter and the rate of motion approximately 5 or 6 vibrations a second.

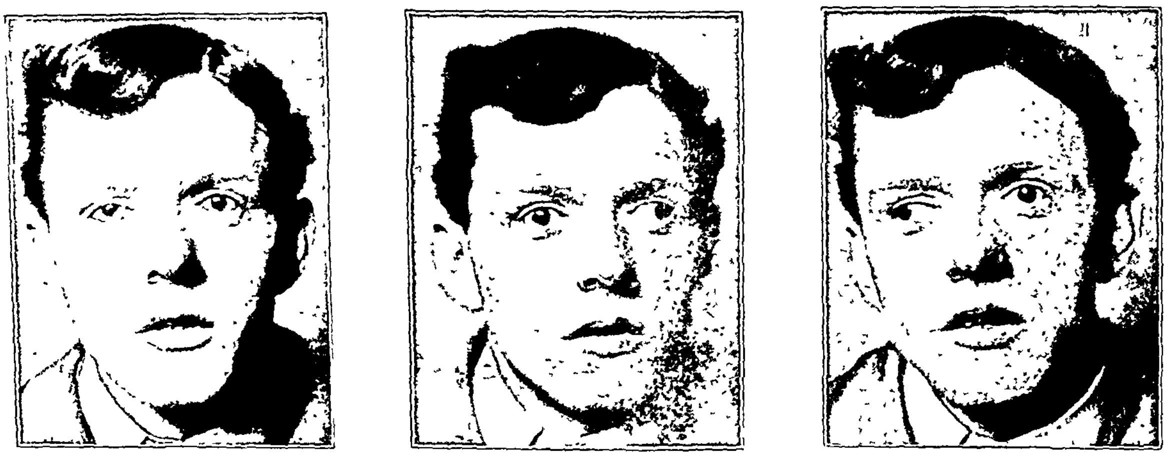

Fig. 1. Eyes in normal position. Fig. 2. Divergence of left eye Fig. 3. Divergence of right eye.

GOULD AND PHILLIPS' PATIENT.

A noteworthy feature of the case was the ability of the patient to arch the right eyebrow independently of the left, or to arch the right upper brow and draw the left down at the same time. He could also close the left upper lid over the eyeball without wrinkling the forehead or the skin of the eyelids, the upper lid apparently falling gently and smoothly over the globe, while the right eye remained open. The patient could also vibrate the alæ of his nose very rapidly and move either ear. All these movements were executed while under the control of the will. I may here mention that one of the most successful and entertaining tricks of a well-known American comic opera comedian is this power to produce bizarre disassociated movements of the eyebrows. None of his stage play is more convulsively humorous than the contortions of his forehead and eyebrows (exaggerated by his "make up" to accentuate the incongruous upper facial grimaces).

Another popular comedian owes much of his successful fun-making to his ability to move one eye independently of the other. Foster remarks that "very few persons are able by direct effort of the will to move one eye independent of the other, though some, and among them one distinguished both as a physician and oculist, have acquired this power." I have seen this faculty exhibited in the person of a negro lad of about 19, a frequenter of the Dispensary of the Emergency Hospital, Washington, D. C., during my service, 15 years ago, as resident surgeon of that institution.

Dr. George M. Gould, of *Philadelphia*, and Dr. William L. Phillips, of Buffalo, have described an extraordinary case of voluntary unilateral divergence in a man of 32 (see illustrations). The patient not only had binocular fixation, but also binocular vision, which, however, was markedly decreased in comparison to monocular vision, likely due to persistent non-use of the binocular position. A remarkable feature of this case was the ability to keep both eyes simultaneously in focus while in the strangely dissimilar positions—one eye straight in front, and the other in extreme divergence. While reading a test-card with the fixing left eye the patient promptly recognized facial grimaces made by the examiner standing in such a position that his face could only be seen by the divergent right eye. Immediately the patient said, "I see you! You can't come that on me." Dr. Phillips also describes another similar case in a man of 60. This patient had taught himself to set type and read proof at the same time without movement of the head. He had never had noticeable diplopia.

In both of these patients the lateral field of vision, when the eyes were diverged, was 220 degrees. The other points in common in these two cases were: The anomaly had existed since birth. They were able to move their eyes in any direction, having absolute control of their external ocular muscles. They were both myopic and had about the same visual acuity under cycloplegia as with the accommodation active, and whether one or both eyes were used in the visual act. When angry they used binocular vision. They were able to converge and diverge when looking either up or down, to the right or left, showing absolutely no deficient innervation of the musculature. Their retinas showed a similarity to the ungulates, in not having a highly developed area, which would suggest a true macula. Although light perception was more acute centrally, it was, however, quite serviceable in all parts of the retina. If it were possible to secure a careful pathologic examination of these eyes, Phillips believes that it would be found that the extraordinary ability of ocular rotations was due to absence of a well-defined macula, which fact would afford evidence in support of the opinion that the macula is absolutely necessary only for binocular vision at the near point.

J. E. Colburn, quoted by Smith, reports a case of involuntary movement in one eye in an engraver of 28. He was accustomed to use his loup before the left eye with his tools distributed to his right side. He used his graver with his left hand and could pick up any tool desired on the table near him without changing the relation of his eye to his work. He had also acquired the habit of fixing with his left eye and rotating his right in any direction required, though not so rapidly and so steadily as when the loup was in position before the left eye. As a result of these curious ocular gymnastics there was produced an attack of cyclitis in the right eye, eight years before, which had recurred three years later, and again in two years. Each attack was more protracted than the preceding. Colburn also mentions the case of a girl, aged 18, who, following an injury to her head in a runaway accident, exhibited rotary nystagmus over which she had perfect control. However, when her attention was not fixed, the oscillations were continuous and considerable.

Such power as the foregoing would indicate inhibition of one eye with volitional innervation of the other, indicating, as Smith sets forth, that the coordinating centers of the two eyes must be influenced along different paths or by different stimuli, or by cortical impulses coming from different areas. He describes a so-called "Z-tract," the fibers of which extend from the neighborhood of the precentral sulcus—the motor area for the eyes—downward between the caudate nucleus and the lenticular nucleus (probably some fibers pass through the corpora striata), thence through the thalamus to the corpora quadrigemina and to the nuclei of the third, fourth and sixth nerves. He notes that nystagmic movements have been produced by passing a probe into the region of the corpora striata and optic thalami. It is remarked that incoordinated movements of the eyeballs are never intimately connected with lesions of the upper and more peripheral parts of the brain. Cerebral hemorrhage involving the basal ganglia often produces conjugate deviation of the head and eyeballs toward the unparalyzed side. Smith also calls attention to the fact that conjugate deviation of the eyeballs occurring as a symptom of cerebral lesion in the region of the basal ganglia is usually indirect and transitory, showing a temporary disturbance only in the tract of fibers connecting the cortex with a center of the brain. The natural conclusion is that in the projection system anatomic examination seems to indicate the connection between the cortical centers of the frontal lobe and with ganglionic centers of the thalamus, and of these with the nuclei of the nerves of the ocular muscles, and later with the coordinating centers.

ABSTRACT OF DISCUSSION.

Dr. M. Wiener, St. Louis, agreed with Dr. Pyle on the necessity for correcting the error of refraction in these cases of nystagmus. He said that about a year ago he had occasion to examine a lady, aged 39, with unilateral nystagmus. The left eye on being fixed was perfectly quiet, while in the right eye there was marked lateral nystagmus. The patient was myopic and astigmatic, but more in the right than in the left eye, whereas the same correction had been given for both eyes. On giving a full correction the nystagmus almost entirely disappeared.

Dr. A. E. Davis, New York, referred to a case of a young girl 7 or 8 years of age, who could voluntarily produce a rapid horizontal nystagmus. Both eyes were involved. There was no refractive error of importance. Dr. Davis said that the patient still had this ability and she was now 17 or 18 years of age. The fundus of the eye was normal and the patient complained of no headache or other ocular symptoms.

Dr. Walter L. Pyle, Philadelphia, called attention to the fact that in spite of all efforts to concentrate and fix the eyes there was still an unconscious, but yet appreciable movement at all times. The assumptions of the older psychologists that there was a definite visual "point of regard," Dr. Pyle said, was now challenged on very convincing experimental evidence. Recently Prof. Raymond Dodge had claimed that instead of a "point" the center of visual interest was a very appreciable "area." This thesis he supported by a few very simple subjective experiments. Dr. Pyle also referred to the authentic reports of cases of voluntary iris, in one of which, by Bechterew, there is described a unilateral voluntary control of the iris. He had found at least a half dozen bilateral instances of this phenomenon in ophthalmic literature. Dr. Pyle reiterated his belief in the importance of the careful correction of refractive errors in all cases of nystagmus, even when there is associate cerebrospinal lesion.

FRACTURE OF PATELLA,

WITH SKIAGRAMS OF RESULTS OF TREATMENT BY SUTURE.*

J. M. BATCHELOR, M.D.
House Surgeon, Charity Hospital.
NEW ORLEANS.

The literature concerning fractures of the patella up to ten years ago is chiefly remarkable for the constantly changing view there represented concerning the proper treatment of the condition. The evil results of patella fractures vary from simple restriction of joint movement to complete loss of function with ankylosis. Such results, partial recovery and impaired function are dependent on two factors: First, improper coaptation of the fracture, and second, prolonged fixation of the joint with resultant atrophy of the quadriceps extensor and shrinkage of the joint capsule. The former condition being dependent on interposition of periosteal tabs, contraction of the quadriceps extensor and intra-articular hemorrhage, rendering it difficult to approximate the fragments.

As early as 1868 v. Volkman attempted to secure close apposition of the fragments by subcutaneous suture, which, with some modification, was later practiced by Kocher, Ceci, Heusner and others, with the inevitable result of impaired function or, at best, a fortuitous union. After the introduction of the antiseptic period with Lister's attempt in 1878 to wire the patella by open suture, and with the subsequent perfection of aseptic technic, surgeons the world over have finally adopted the method of open suture as being the only method of removing the mechanical hindrances before mentioned.

I have operated in the past twelve years in eleven cases. My first operation was performed in 1897 and consisted in wiring the patella with silver wire. The patient in this case was admitted to the hospital May 17, after sustaining a fracture of the patella by indirect violence. He stated that two years before, fracture of

---

* Read before the Orleans Parish Medical Society, July 27, 1908.

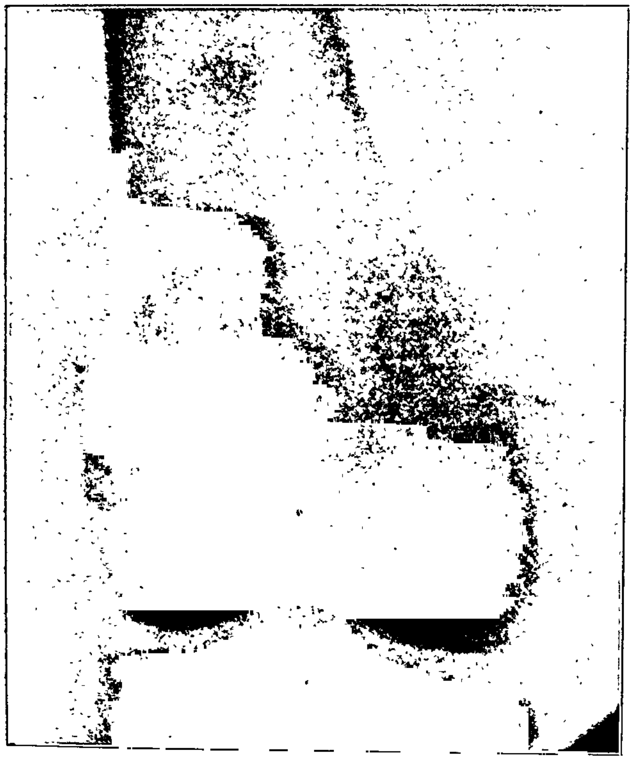

Fig. 1 (First Series).—Skiagram of fracture of patella, showing a separation of ⅜ in. Operation done under chloroform anesthesia.

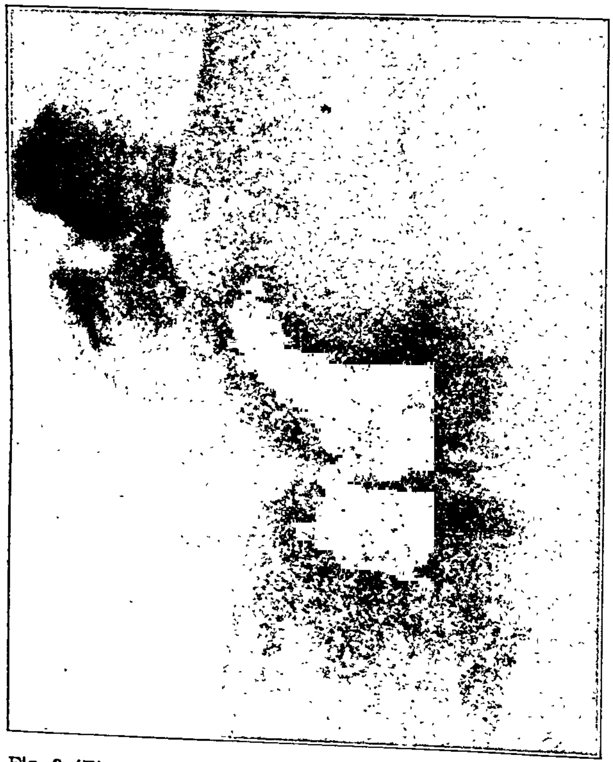

Fig. 3 (First Series).—Skiagram of fracture of patella, showing separation of bony parts. Operation under local analgesia (Schleicht).

the same patella had occurred and this had been treated by splint and bandaging. In this case, as in all others, with one exception, I allowed forty-eight hours to transpire before operating, so as to allow complete cessation of hemorrhage and thereby lessen the difficulty of operation.

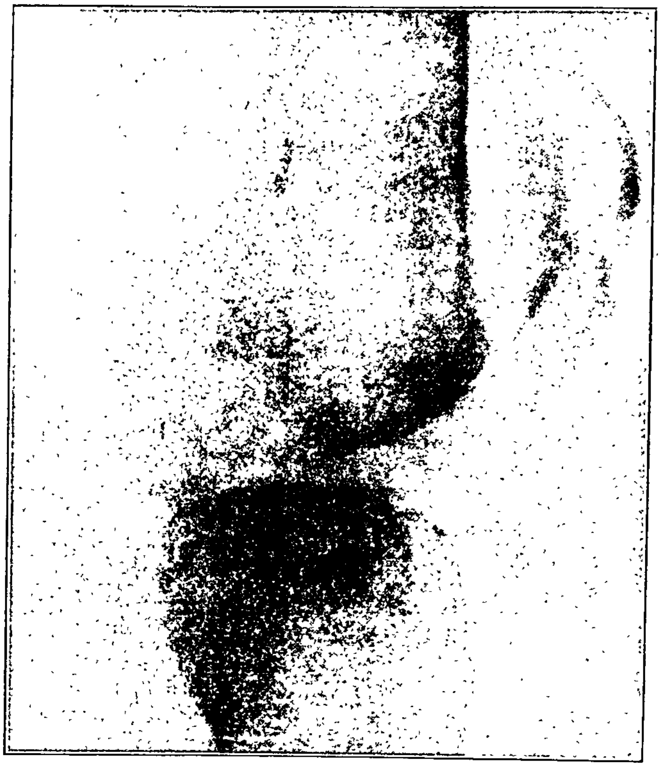

Fig. 2 (Second Series).—Skiagram of the knee joint shown in Figure 1, taken fourteen months after fracture. Bony union has occurred.

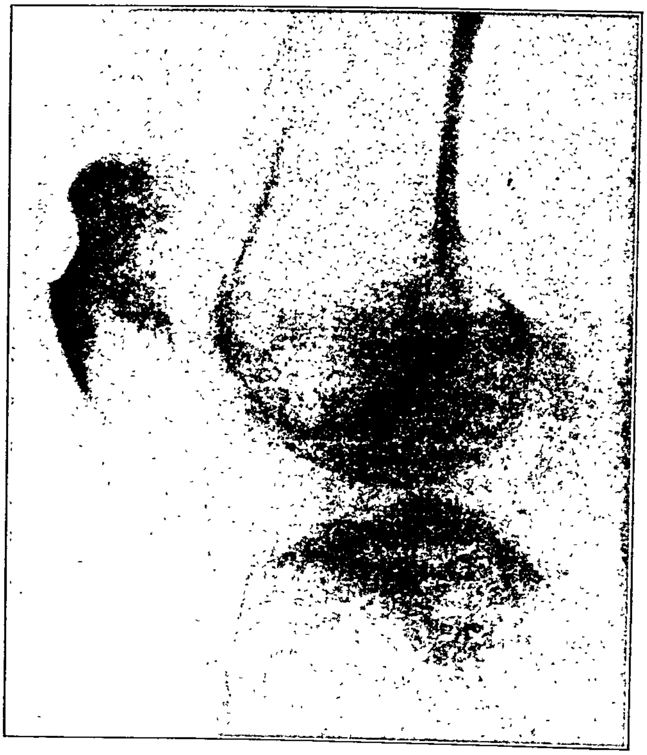

Fig. 4.—(Second Series).—Skiagram of knee joint shown in Figure 3, taken two years after fracture. Bony union complete.

OPERATIVE TREATMENT.

My subsequent experience in the second case, in which I operated immediately after the injury, convinced me of the advantage to be gained by a forty-eight hour wait before operation. In this second case the constant oozing of blood in the joint, rendering frequent sponging necessary, left me in some doubt as to the wisdom of closing the joint in which I had reason to believe a collection of blood would finally be left. My technic in all subsequent cases, as in the first, has been to confine the patient to bed for forty-eight hours after the injury before operating and during this time to fix the joint and apply an ice-bag. The difficulty of operation is much reduced by this wait, sponging being less necessary and much traumatism of the joint obviated.

During the entire operation it is my custom to run a 1 to 20,000 bichlorid of mercury solution through the joint, obviating the necessity for sponging and preventing sepsis. The suture has been, indifferently, catgut or kangaroo tendon except in the first case, in which the patella itself was wired with two silver wires. In every case immediate and complete closure of the joint was done and primary union resulted.

POSTOPERATIVE TREATMENT.

The postoperative treatment consisted in immobilization of the joint by a posterior gutter splint with confinement in bed for fourteen days, after which the patient was allowed to get up and walk, the leg remaining in the splint. The intra-articular pressure from weight-bearing I have found to aid greatly in overcoming stiffness of the joint and in causing resorption of adhesions that may have formed, and I believe it contributes greatly to restoration of the joint function. I have rarely found it necessary to practice passive motion for more than seven days.

In the skiagraphs (Figs. 1, 2, 3 and 4) of two of these cases, the first series (Figs. 1 and 3) were taken four weeks after the operation, and the second series (Figs. 2 and 4) were taken at periods of fourteen months and two years later, respectively. It will be seen that in each case in the first series (Figs. 1 and 3) of skiagraphs taken four weeks after operation there appears to be a separation of the fragments, in one case (Fig. 1) an apparent separation of at least three-eighths of an inch. It will be observed in the second series (Figs. 2 and 4) of skiagraphs that there is bony union in each instance. Three of the patients in these eleven cases were operated on under local analgesia (Schleich). In these eleven cases ten of the patients have perfect function of the joint, being able to flex the limb to the extreme and to mount a chair while standing close to it.

CONCLUSIONS.

My observations from the standpoint of these cases and of the skiagraphs of seven of them lead me to the following conclusions:

1. Bony union rarely takes place before thirty days.
2. Bony union is possible where there is, after suture, a separation of the fragments equal to three-eighths of an inch.
3. Whenever general anesthesia is directly contraindicated such patients may be operated on under local analgesia and bony union confidently expected.
4. The essential requirements of the operation are, first, preliminary fixation of the joint for from forty-eight to seventy-two hours to allow complete arrest of hemorrhage: second, suture of the lateral tear of the capsule, thereby restoring the reserve extensors and obviating the danger of atrophy of the quadriceps; third, absolute asepsis and immediate closure of the joint without drainage.

GENERAL PARESIS IN CHILDHOOD.*

ARTHUR WILLARD FAIRBANKS, M.D.
Assistant Physician for Diseases of the Nervous System at the Children's and City Hospitals; Instructor in Clinical Medicine, Tufts College; Visiting Physician to the Floating Hospital for Children.
BOSTON.

I wish particularly to preface this paper by the statement that my remarks apply to paresis in childhood and are based on a study of the disease at this period of life.

Paretic dementia, having its onset previous to the age of 16 years is, if one may judge from the space given to the subject in the text-books, of great rarity; and we find, in fact, that previous to the last fifteen years the paucity of cases reported in the literature seems to have justified the scanty attention accorded to the affection by the text-books.

Has this seeming infrequency been actual or only apparent? There are many factors that may explain the apparent but not actual rarity of this affection.

In the first place, we are dealing with an affection whose chief or most obvious symptoms are mental. I believe it is not an exaggeration to say that fewer medical men are conversant with the symptoms of mental disease and their significance, or inclined to give to such cases as come under their observation that inferential attention and study that they would devote to any other affection, than is the case in any other department of medicine.

Secondly, the disease is often extremely insidious in onset. There is rarely anything alarming to the average parent in the early months of the disease. The symptoms are ascribed to indifference, laziness, nervous irritability or ill temper. So gradual is the progress of the mental deterioration that the disease is usually well pronounced by the time the family physician is consulted; but even then the full import of the clinical signs and the significance of their duration may not be recognized. The pronounced clinical features of the affection, especially those of motor character, naturally more obvious to the general practitioner, are often ascribed to shock, or may be considered as the sequelæ of some preceding injury or disease. The parents are assured that the child's brain has been injured and that there is nothing to be done. The advance of the disease is so unobtrusive that the parents delay seeking special advice, and the child dies of some intercurrent disease, and the case is lost to science. In other instances the patient is committed to an institution at so late a period of the disease that, on account of the forgetfulness or indifference of the parents, or lack of thoroughness on the part of the history taker, the exact and early onset of the affection may not be apparent. I am convinced that it is a safe inference that all cases of mental disease in childhood actually antedate considerably the onset assigned by the family.

Finally, without question many cases have terminated their course in institutions, and others are at the present time inmates, that have not been and will not be reported on account of lack of interest or procrastination on the part of the medical officer or on account of the pressure of his routine work. When we consider these facts we are justified, I think, in assuming that general paresis is somewhat more frequent in childhood than might be inferred from the literature, although without doubt a relatively rare affection.

---

* Owing to lack of space, the article is here abbreviated by the omission of the report of a case. The complete article appears in the Transactions of the Section and in the author's reprints.

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

The number of reported cases is so small that it is hardly possible to assert positively that the disease in childhood is increasing in prevalence. In the very large clinic at the Children's Hospital the affection is very rare, and no evidence of any such increase is noticeable. But it is of interest to note that in the series of which I give an analysis at the end of this paper 89 per cent. were reported within the last fifteen years and 65 per cent. within ten years. None of these children was over fourteen years when the first symptoms were noticed. If I had included the fifteen and sixteen year old patients, a very remarkable increase of cases reported within the last few years would be apparent. This is in part due, I am sure, to the very greatly increased interest in the study of the manifestations of disease in childhood. but my personal feeling is that there has actually been an increase of the disease itself, but not as yet of sufficient proportions to be noticeable in any one clinic.

The earliest apparent onset of which I am aware was in a six-year-old child reported by Marr.[1] This is so very early that I should doubt the case, had the autopsy not been obtained. As childhood advances the affection increases in frequency, slowly at first, but progressively, up to the fourteenth, fifteenth and sixteenth years, at which period by far the greater number of instances occur, or at least have that period assigned as the date of their onset. From this age onward there is a very abrupt decline in the likelihood of the occurrence of the disease for a period of several years, at the end of which time there is again an increase in its prevalence, slow and gradual, to the thirtieth year.

CLINICAL PHENOMENA OF THE AFFECTION AND THEIR VARIANCE FROM THE ADULT TYPE.

By the terms "general paresis," "paralytic dementia," "juvenile or infantile dementia," "progressive general paralysis of the insane," occurring in childhood, we mean an affection whose initial characteristic is cessation in the evolution of the intellect and deterioration of its function, and whose further course is accentuated by a progressive disintegration of the higher cerebral centers, with its resultant abnormal psychical phenomena, and by coincident disturbances in the motor and very rarely in the sensory spheres, and characterized pathologically by a meningoencephalitis with atrophy and degeneration of the parenchyma and proliferation of the neuroglia of the subjacent brain.

No one of the terms applied to this affection is really acceptable or correct, especially when applied to the affection as we see it in childhood. For, while these children are always demented. they are not invariably paralytic in the restricted interpretation of the term, and while all of them are abnormal mentally and most of them are eventually paralyzed, they are not always insane in the strict definition of that term; while the title "juvenile" or "infantile dementia" brings to mind certain defective mental conditions in children, either of congenital character or otherwise, and having nothing whatever to do with the affection which we are studying. Some term should be devised to convey to the mind the distinctive character of the affection, and until then the title, general paresis, is perhaps less objectionable than any of the others.

The characteristic clinical features of the disease in childhood are, in its onset, failing memory, depreciation of intellectual power and change of character, the first two being usually noticed in the cessation of progress at school. These symptoms are progressive and are soon associated with tremor of the face, lips, tongue or extremities, of varying extent and degree; disturbance of muscular coordination, disorders of speech, disturbances in the gait, change in size and reaction of the pupils, and exaggeration of the deep reflexes and often of the superficial as well. As the disease becomes well established, delusions, hallucinations and morbid fears not infrequently appear. As the affection progresses the mental state becomes one of apathy and depression, alternating with occasional outbursts of passion or excitement, sometimes maniacal, or, without such outbursts, it remains one of apathetic content or indifference. External impressions become superficial and transient. Even occasions of great grief or anxiety in the household bring forth no response from the child. This is often in most striking contrast to the previous affectionate and sympathetic disposition of the child. Deeper and deeper the child sinks into imbecility; it becomes more and more unsteady and tremulous; weaker and weaker on its legs; incapable of clothing or feeding or helping itself in any way; unclean and without control over the sphincters; and, finally, bedridden, more from general tremulousness and inability to initiate and control muscular movement than from definite localized paralysis. Soon after the state of bedridden helplessness is reached, contractures ensue, bedsores develop and in a condition of advanced emaciation the victim finally dies of exhaustion or intercurrent disease, occasionally with terminal convulsions.

Intercurrent in the course of the disease, general or localized epileptiform convulsions sometimes occur, and palsies of varying extent and degree are not uncommon, especially in the part either exclusively or most markedly affected by the epileptiform seizure. These palsies are more often partial than absolute. They may remain permanent or they may slowly clear up, notwithstanding the advance of the disease, in which case they usually recur sooner or later in the same part, not often in some other part of the body. Especially is this so in the local paretic conditions following epileptiform convulsions, at some subsequent recurrence of the spasm.

The sudden, frequent and transient implications of the cranial nerves, so characteristic of cerebral syphilis, do not occur in this affection. a point of considerable importance. as will be seen when we come to speak of the differential diagnosis. Cranial nerve palsy, when it occurs, usually involves some branch of the third nerve.

Optic atrophy is quite frequent, but not sufficiently so to make it a prominent feature of the symptom-complex. While usually a feature of the well-developed stage of the affection, motor disturbance may occur very early, or in rare instances may seem to usher in the disease. Tremor and incoordination are quite frequently early phenomena, and occasionally well marked paralysis or convulsions may take place early in the course of the disease. or may be obtained in the history as occurrences long preceding the apparent onset of the dementia.

---

[1] Case 34 of the Summary.

Wherein does this disease in the child differ from the adult form? In many features, but first in a very striking particular, namely:

The male sexual predominance, so characteristic of the adult type, does not hold true in childhood. The disease is about equally divided between the sexes. Thus, of a large number of cases studied, there were a series of forty-two authentic cases, the origin of which in every case occurred before the end of the fifteenth year, that is, well within the period of childhood; and of these twenty patients were boys and twenty-two were girls.

Second. The course of the disease is somewhat longer in the child.

Third. In the infantile type, well-defined, true delusions of grandeur, expansive obsessions, are rather rare. They do, however, occur, but are then limited in range, due probably to the child's previous inexperience in and consequent ignorance of the social, political and business relations of life. Other and more common delusions are also of simple character and much more transient than in the adult, not nearly so persistent.

Fourth. The emotional element is the essential and predominant feature of the infantile type. Causeless excitement, unprovoked laughter or weeping, screaming, and morbid fears interrupt the apathetic contentment. Excitement is prone to occur or be especially marked at night.

There is no doubt that the disease in the child is less complex and presents, as Watson says, a purer type than in later life.

SPECIAL FEATURES.

One of the most characteristic of the clinical phenomena of this affection is the muscular instability, that tremulous condition of muscular equilibrium, sometimes constant, sometimes occurring only on attempt at voluntary movement, and always greatly increased by such attempt, occurring in the face, lips, tongue or extremities mainly, but evident more or less in the body as well. With this tremor there is quite frequently, but by no means invariably, a distinct inability properly to control or to coordinate muscles or muscle groups for complex action. Both of these conditions seriously interfere not only with the action of the hands, but with the gait and the function of speech, and add to the special disturbance of the gait and speech that is peculiar to the disease.

The gait may be spastic or ataxic, as in tabes, and is occasionally distinctly staggering; but the most common characteristic, in the child, at least, is the unsteadiness of the gait. To overcome this unsteadiness, the feet and legs are placed wider apart than normally, and the child's attempts to walk often recall to mind the early efforts of the infant in learning to walk. As this condition increases in intensity, the child becomes more and more afraid to trust itself to walk alone.

The speech is tremulous, slow and often hesitant, and of monotonous character, with little or no change of inflection. It may be lisping or stammering and occasionally the speech has a somewhat explosive character, but this is not very marked or common. Syllables and words are often transposed or elided. This phenomenon is probably purely mental in origin, but many of the other peculiarities are due to difficulty in initiating the coordinate muscular action necessary for the emission of a syllable or word, or to overaction of certain muscles and insufficient action of others, involved in the function of speech. The slowing and hesitation may be due to the use of indirect paths in the brain between the auditory and visual memory centers and the motor centers for speech, necessitated by the destructive progress of the disease. Sometimes preceding or during speech there is overaction of the facial muscles, especially about the mouth, or fine twitching of these muscles occurs. Toward the end the speech usually becomes either impossible or a mere jumble of unintelligent sound.

The features are deficient in expression, and often do not respond to emotion which the child seems to feel. It is not quite accurate to describe them as expressionless. In some cases there is a peculiar suggestion of anxiety in the countenance, which is sometimes accentuated by the furrowed condition of the forehead, which may by itself alone give a distinctly scowling cast to the expression, very different from the blank stolidity and complete facial inaction seen almost invariably in the adult. The pupils are usually dilated, and as a rule unequal, and always sluggish or inactive to light, and, not so very infrequently, also to accommodation. They are rarely both contracted, although, somewhat more commonly, one may be so for a time, in the earlier stages of the disease. Occasionally the light reflex is lost on one side before it fails in the other eye. The deep reflexes are always exaggerated in the uncomplicated case. When in such cases they are not so found, it is because of lack of relaxation of voluntary muscular tension, or on account of rigid muscular contracture. Clonus and the Babinski sign are occasionally to be elicited, but are not essential or even common features of the symptom-complex. The superficial reflexes are also sometimes increased. The Romberg phenomenon does not occur in the affection, at least in the child. There is in some instances a marked increase of muscular irritability.

Sensory disturbance is not a feature often present, although some diminution in reaction to pain may occasionally occur, probably from mental obtuseness rather than from actual anesthesia. Headache is not sufficiently frequent to be considered as either an essential or common phenomenon. When it occurs, however, it may be a cause of bitter complaints.

MENTAL STATE.

In the early stage of the disease failing memory and alteration of character usually constitute the initial signs of the impending disintegration of the mind. A child previously affectionate, sympathetic and tractable, companionable with its fellows, fond of its work and its play, and more and more interested in its increasing complexity, incident to the evolution of childhood, becomes less demonstrative, less interested in and more and more indifferent to its environment. External events fail to excite the accustomed attention, and irritability and resentment take the place of affection, sympathy and docility. Little acts of affection or courtesy once practiced are less and less evident, and childish duties learned and once well performed are neglected and forgotten, and trivial incidents of daily life cause irritative reaction out of proportion to their importance. The necessity of mutual compromise and concessions to the requirements and possibilities of its environment, formerly understood by the child, is now disregarded. New impressions make but superficial indentation on the mind, and such impressions are soon lost, or, if retained for a time, are wrongly interpreted, and not correlated with other impressions in proper ratio.

It is the power of ideation, the logical association of ideas based on experience and on relation with the external world, the proper sense of proportion, the judgment, the higher inhibitive power, the balance of the mind, that is overthrown. The more extensive the previously acquired perceptions have been, the greater and more conspicuous is the wreck of their proper association or correlation with one another. Consequently the brighter the previous intellect of the child the more striking is its early unbalancing and subsequent overthrow.

Delusions and hallucinations are comparatively frequent, but they are of simpler type than those of later life. The following are illustrative:

Hallucinations.—A 13-year-old girl frequently imagined some one was at the door and often ran to open it (auditory?); thought an elephant was at a corner of her bed, and pointed to what she said were men in an empty room (both visual). A 15-year-old girl thought she had money, and when convinced that she had none accused a sister of stealing it; refused food "because she couldn't swallow and all her teeth were falling out," and her father had "put a jug down her throat" and it "was still sticking there." An 11-year-old girl thought a boy told her that a little girl acquaintance was dead and sat at the window for an hour, "looking out at the coffin," although the child in question was not even ill (auditory and visual). A 15-year-old girl declared "the dear lady" appeared to her and "told her she was going to take her to heaven" (visual and auditory).

Delusions.—An 11-year-old girl thought a little boy, living across the street, was beating her. One day her mother heard her screaming in an adjoining room, "Go away with you," "Take it away," and found her pointing to a fly crawling on the table and saying it was a big dog and it frightened her. When at home she imagined that she was away. Another girl thought dogs were following her. A boy gazed for long periods into the palms of his hands and thought he was reading a newspaper. A girl was "acquainted with the queen."

Closely associated with hallucinations and delusions, and often incapable of being separated from them, are morbid fears, as in the case of the girl who constantly worried because at her first communion she "did not confess all her sins," also she "prayed too much," and the devil appeared to her and asked her "to sell her soul." These morbid fears are usually in striking contrast to the child's indifference to events of actually tragic character in its environment.

Marked delusions of grandeur and pronounced states of exaltation are very rare.

While failing memory is often one of the initial signs of the disease, there are occasional instances in which the memory for things learned by rote is long preserved to a remarkable degree. This is also mentioned by Thomson. In the case here reported, under my own observation, five months before death, at a period when all of the other signs of dementia were well marked, the boy recited "Barbara Frietchie" with only two or three mistakes, and these he recognized and corrected himself. Recognition of friends either by sight or voice is also sometimes present for a much longer period than the mental state otherwise would lead one to expect.

A striking feature of the childhood type of this disease is the cessation of sexual and physical development. Sexual growth does not occur after the onset of the affection, the sexual organs remaining infantile in type, and in the girl menstruation does not occur, or if already established it soon ceases, while the physical development advances but little beyond the point reached at the advent of the first well defined symptoms of the disease.

DURATION.

The course in children is steadily progressive. Only now and then is a case seen in which slight remissions occur, but they are brief. On the other hand, although the decline to complete dementia is progressive and relatively rapid, the demented stage itself is relatively long, so that the actual duration of the affection from onset to death averages much longer than in the adult. So decidedly is this the case that in those instances of apparently very short duration it is well to look with some doubt on the period assigned by the relatives as that of its onset. Then, also, in children of duller or slower mental caliber the disease is less apt to be recognized as early in its onset as in the brilliant mind. This in itself greatly modifies the apparent duration of individual cases. It is also probably the reason why cases in which the onset is early seem to run a longer course than those in which we are obliged to accept an apparently late period for the advent of the initial symptoms.

In an affection, the duration of which varies so very greatly, it is of no practical value to assert an average duration obtained by dividing the sum total of the years of duration by the number of cases involved. The figure so obtained tells us nothing and is misleading. What does it avail us to know that of a series of cases whose individual duration varies from one to nine years the average duration is four years? For that does not tell us whether any given case will last the maximum or the minimum of these periods. All that we can say of this disease is that it may last any period from one to nine years. Nothing more definite is possible.

DIAGNOSIS.

If the history is taken with painstaking care, with careful and skilful cross-questioning of the relatives, and our examination of the child conducted with critical thoroughness, there is but a single other disease that can be mistaken for the one we are considering, and that disease is cerebral syphilis. Even here a critical consideration of the course of the affection in all its details, of the character of the onset, course and duration of the individual phenomena, will usually enable us to differentiate the two conditions. When we remember that many of the phenomena of active syphilitic disease of the brain are due to arterial accidents and disturbances in the cerebral circulation from vascular disease, resulting in a cutting off of the blood supply to certain restricted areas of the brain, usually sudden in character and often very transient in duration, and manifested clinically by sudden, circumscribed and fleeting palsies, now here, now there, occurring and vanishing in often most eccentric manner, by vertigo and syncopal attacks, and *transient* disturbances of memory, speech and consciousness; when we remember that in those instances whose chief clinical phenomena are due to meningitis, it is a meningitis localized, or at least concentrated, at the base, with consequent involvement of the cranial nerves and resultant multiple, eccentric and often fleeting palsies of these nerves; and, finally, when we bear in mind that circumscribed gummata, very rare in the child, present clinically the focal signs of intracranial tumor, we shall be saved from many an error in differential diagnosis.

The peculiar manner of onset, erratic course and often very transient character of the phenomena in cerebral syphilis, and their peculiar association with one another, afford quite a different clinical picture from that seen in the ordinary case of paresis. While cerebral syphilis *in toto* is progressive, its individual symptoms are not necessarily so. Moreover, while paralytic disturbances of speech are common in cerebral syphilis, they are usually of brief duration, and the peculiar progressive alteration of speech found in general paresis is practically unknown in this disease. The palsies of paresis, while they may be sudden in onset, are usually partial in character, amounting often times to little more than a muscular weakness, and, although they not infrequently clear up, they do so gradually, and if they recur they tend to reappear in the same part of the body, not in some totally different portion, as in cerebral syphilis. While we may have, at some time or other, in either of these affections, nearly all the symptoms seen in the other, nevertheless the individual symptoms and the aggregate of the phenomena, for any considerable period in the course of the disease, are never similar, and the steadily progressive course of paresis, with the mental disintegration always in the foreground, and the increasing muscular instability and fine tremulousness, associated with disorder in writing and speech, form a clinical picture not likely to be mistaken by a careful observer for active syphilitic disease of the brain.

There are, however, occasional instances in which the absence of special phenomena, peculiar to either disease, and the predominance of mere mental deterioration, render impossible for a time a differentiation between the two affections. Especially may cases seen very early in their course, before the advent of symptoms of special significance, remain for some time doubtful. Cases first seen so late that all peculiar phenomena are obliterated in the general wreckage of the mind may require, especially in the absence of an adequate history, a postmortem examination for their diagnosis.

There can be no possible confusion between well-developed cases of paresis and tabes: and those instances of paresis with tabetic symptoms are simply cases in which the sclerosis of the posterior columns of the cord, a certain degree of which is present in a large percentage of instances, is earlier, or more extensive, than usual. They are simply cases of combined disease, and, at the most, it may be early in the beginning, merely a question which features, the cerebral or spinal, are going to predominate in the subsequent course of the disease. One of the earliest cases of paresis in childhood ever reported was of this mixed type. It was reported by Strümpell, and is the eleventh case in my summary.

PATHOLOGY.

The essential pathologic changes are: a meningo-encephalitis, in which the leptomeninges are thickened, cloudy and more or less opaque, and frequently adherent to the underlying brain; increase in the intermeningeal fluid; atrophy and disintegration of the cortical ganglion cells, and degeneration of the white fibers; proliferation of the neuroglia; granular ependymitis, with increase of the intraventricular fluid, and dilatation of the ventricals; atrophy and shrinking of the convolutions of the cortex.

With these typical changes there is occasionally associated a pachymeningitis, with or without adhesions to the cranium or the subjacent pia-arachnoid, and occasionally a subdural false membrane, and sometimes areas of hemorrhage. The pia-arachnoid, in the majority of cases, is adherent to the underlying cortex, and decortication usually occurs when these adhesions are separated. The two hemispheres are sometimes adherent to one another. The meningitis is very marked over the cortex, but slightly marked at the base. The shrunken condition of the convolutions often leaves the sulci widened. The atrophy and shrinking of the convolutions is especially noticeable in the anterior half of the hemispheres.

The brain, as a whole, is usually, though not invariably, increased in density, but always greatly decreased in weight. Occupying the places of many of the nerve cells of the cortex are proliferated and hypertrophied neuroglia cells with thickened processes. The granular condition of the ependyma is especially pronounced in the fourth ventricle, where the granulations are much larger and, therefore, more conspicuous than in the lateral ventricles. The intracerebral vessels frequently show a greater or lesser perivascular infiltration with round cells and increase in the nuclei of the adventitia, and sometimes actually thickened walls.

Changes similar to those found in the cerebrum may be present in the cerebellum.

The inner and outer tables of the cranium are frequently greatly thickened, sometimes irregularly so, and the cranium as a whole often increased in density.

In the cord the membranes are frequently thickened, and there may be a partial degeneration of the pyramidal tracts, and quite often a sclerosis of the posterior columns. These changes are usually more developed in the upper part of the cord. Degeneration of cells in the gray matter with increase of neuroglia is also sometimes seen in the cord. The so-called spider cells, on which so much stress was formerly laid, but which are now generally recognized as merely hypertrophied neuroglia cells, may be found in the case of poliomyelitic degeneration, as well as in the cerebrum and cerebellum.

ETIOLOGY.

I have said that the clinical type of any disease in childhood is purer than in adult life. We have seen that this is true of the disease we are considering. The same truth applies to the etiology of any disease, and it is true of the etiology of paresis. The old bogies that for years have been employed to befog the etiology of nearly every long-standing or chronic and more or less inexplicable disease in the adult, vanish in the light of the simple history of similar disease in childhood. Given, therefore, such a chronic and seemingly inexplicable disease, occurring in the child as well as in the adult, I believe that we are safer and on firmer ground for the drawing of logical inferences as to the character and causation of that disease when we study it in the child rather than in later life.

No disease, perhaps, has been so overburdened with etiologic factors as general paresis. This is because it has been studied in adult life and the inferences drawn have been based on cases occurring at this period of life, when such factors are most numerous and at the disposal of any one ready to accept them as the direct exciting causes of the disease. Among these supposedly direct exciting causes of paresis may be mentioned phthisis, alcohol, business worries and cares, the "strenuous life," emotional stress and shock, and sexual excess.

What becomes of these factors when we study the affection in childhood? Surely, as direct exciting factors, we are obliged to eliminate all of them with the possible exception of the first two.

As far as tuberculous processes are concerned, postmortem examinations, in children dying of paresis, rarely show any tuberculous lesion of such location or advancement as to render its influence in the etiology of value. What about tuberculosis in its hereditary relation to the disease? For about fifty years tuberculosis has been steadily decreasing among civilized people, notwithstanding our greater refinement and accuracy of diagnosis. Yet paresis is increasing greatly in prevalence, and particularly among the class least liable to phthisis. Moreover, in those races in which tuberculosis is extremely prevalent, paresis is extremely rare, and the prevalence of phthisis in the antecedents of children afflicted with paresis is no greater than can be obtained in the family history of many other patients.

Were alcohol an exciting cause of paresis, the affection would be much more common than it is in the adult. Moreover, were it a factor through hereditary influence, it would be impossible to explain why general paresis has not been one of the common affections of childhood, for alcohol has been used and abused for many generations. It is, indeed, a question whether its actual abuse was not as great (or greater) a hundred years ago as now. Moreover, there is no constant, or even very frequent, discovery in the organs of adults, dying of paresis, of those organic changes, usually regarded as characteristic of alcoholic excess. Finally, it may be remarked that paresis does not show its greatest prevalence in the class most addicted to extraordinary and long-continued abuse of alcohol. I believe that the frequent history of alcoholic abuse found in the child's antecedents, over and above what might be found in the history of any other disease, is to be accounted for on the basis that it is the ordinary concomitant of a more or less dissolute life, either its cause or effect, and that such dissipation and alcoholic excess merely renders its victims more exposed to risks of the infection that is the ultimate and probably the only cause of the disease we are considering.

Moreover, neither coincidence nor any of the above enumerated, frequently asserted, etiologic factors can explain the extraordinary frequency of occurrence in the patient, or in the other children of the family, or among their antecedents, of incidents or conditions well recognized as the stigmata of well-defined and specific constitutional disease.

When paresis is studied in the adult this mass of convincing evidence is lacking, and what might be of value to us concerning his own personal experiences we frequently fail to obtain, either through ignorance, forgetfulness or design on the part of the patient, on whom we must depend for all data bearing on his case, except the objective features he may present at the moment of our examination. When, however, we have to deal with a child, all the circumstantial and direct evidence, personal, familial and antecedent, is at our disposal for analysis and interpretation. We are not, in other words, dependent on the patient alone for our deduction as to the origin of his disease. The more carefully we obtain the family history of infantile paresis by skilful and exhaustive cross-questioning of the relatives, the more thoroughly we examine the father and mother, and especially the other children of the family, the more convincing will be the evidence that we are here dealing with the late results of a specific constitutional disease, and that that disease is syphilis.

This collateral evidence will consist of the presence, at some time in the life-history of one or both of the parents or grandparents, of conditions whose specific significance is beyond doubt. When we do not obtain from the father direct acknowledgement of syphilitic infection, we may extract from his history the fact that he has at some time suffered from disease of the skin, bones or glands, from alopecia, from nocturnal cephalalgia and osteoscopic pains, from ulceration of the throat or soft palate, or affections of the eyes, especially the cornea, and that these conditions have promptly disappeared on the administration of internal remedies or inunctions. Or we may obtain similar facts from the history of the mother, with the addition, however, in her case, of the valuable evidence afforded by the extraordinary deleterious influence of syphilitic disease on her maternal functions and the lives of her offspring. Repeated unexplained miscarriages, still-births and early infant mortality, or the early appearance in her children of syphilides, pemphigus, obstinate rhinitis, unexplained marasmus, blindness or deafness, and repeated convulsions, often terminating in death, or her statements that two or more of her children have succumbed to hydrocephalus or meningitis, or were at one time afflicted with the same and recovered under treatment, are all of most valuable import. In regard to the patient and the other members of its immediate family I may repeat here what I have already said concerning cerebral syphilis:[2]

> If we can not obtain from the parents information of specific infection in themselves or symptoms of infection in the early history of their child, we must endeavor to find on the body of the child itself some evidence of previous disease, or, failing in this, seek for such evidence in the other children of the family, in the shape of recent or old traces of syphilitic lesions. . . . In not a few instances nothing in the history or examination of the patient or the family will be found to enlighten us in our doubt, but suddenly an interstitial keratitis appears on the scene and yields the clue for which we have vainly sought. Or keratitis may occur in one of the brothers or sisters, or a chance ophthalmoscopic examination may reveal in one of them, or in the patient, evidence of chorioiditis, reminding us that in searching for specific stigmata in the shape of deformities of the teeth and nose, scars about the mouth or in the throat, impairment of hearing, etc., the fundus as well as the cornea of the eye should be invariably examined, in the other children as well as in the patient.

Were syphilis not the important factor in the causation of this disease that the facts show it to be, we should find that there would be no direct ratio between the care with which we search for specific etiologic data and the success that meets our efforts, whereas the ratio is direct and convincing. Our percentage of failures in obtaining such data is not any greater than it is in the history of other patients with conditions whose positive syphilitic character is beyond question.

Finally, in some instances in which the clinical history lacked this specific evidence, the postmortem examination has not only confirmed the diagnosis of paresis, but has demonstrated in organs, other than those of

---

the nervous system, unequivocal lesions of syphilis. If we make our search ever more rigid and exhaustive, we shall steadily reduce the still remaining small percentage of cases in which specific evidence seems to be entirely wanting, and we shall reach the eventual and inevitable conclusion that syphilis is the one and sole direct cause of this disease, as was asserted by that clear and accurate observer, Fournier,[3] years ago.

General paresis is not more common in children mentally defective from birth. The majority of cases occur in children of average mental ability previous to the onset of the disease.

The "stress of puberty and adolescence" has been thought by some to be of importance in the determination of the onset of juvenile paresis. There can be no question but that, at the present time, the majority of cases seem to have their origin at about this period. We are dealing, however, with a so-called parasyphilitic affection requiring ordinarily from ten to fifteen years to develop. As the specific infection is inherited or, as may rarely happen, acquired very shortly after birth, the age of puberty is about the time when we should expect the advent of the disease. Its incidence at this period is due, I believe, to this fact and not to any peculiar influence offered by this period of life in the determination of the onset of the affection.

Of great interest is the frequent occurrence of similar disease in the other members of the family, especially in the parents or grandparents. Often when we do not obtain a positive history of the occurrence of paresis or tabes in others of the family we shall learn of cases of "dementia." "brain trouble," "insanity," etc., which would undoubtedly prove to be general paresis if we could learn all the particulars. In many cases not included in my summary on account of the age of onset having slightly exceeded fourteen years, this same occurrence was very striking.

In a relatively large number of instances injury in one form or another is assigned by the relatives as the cause of the onset of the disease. In this connection I may repeat here what I have already said of similar occurrences apparently preceding the onset of cerebral syphilis,[2] in which the same fact is often noticed:

> What is it that induces in one case the concentration of the effect of the specific poison on the brain while another individual enjoys complete immunity from any cerebral implication? This is a problem to which no complete solution is at present possible. Interesting, however, in this connection are a number of cases in which the apparent initial phenomena have followed a blow or a fall on the head. They are not so common that we may refuse to believe them more than coincidences, occurrences brought into the picture by the common tendency of the parent to attribute everything to an accident. Nevertheless they can not be entirely ignored. It may be that, in the one case, the brain by inherited or by acquired deficiency in vitality or in power of defense, becomes a *locus minoris resistentiæ*; while, in another instance, concussion by its circulatory and nutritive disturbances produces a similar condition.

Paracelsus says: "Syphilis takes, in every man, the character of that disease to which he is inclined by hereditary or other predisposition."

I present here a condensed summary of thirty-eight instances of general paresis occurring well within the period of actual childhood. Not only are these cases, from a clinical standpoint, unquestionably typical instances of the disease, but in twenty-nine, or 76 per cent., we have the pathologic diagnosis to confirm the clinical. A study of these cases will afford an absolutely accurate idea of the affection as it manifests itself in childhood.

---

[3] La syphilis héréditaire tardive, 1886.

I offer this tabulated summary, therefore, without further comment, for the consideration of all who may be interested in the subject, but who may not have the time or the facilities to study the matter in the original articles.

It is my duty and pleasure to express how deeply I am indebted to those who have reported these cases, for the free use I have made of their material. To many others not here mentioned I am equally under obligation.

ABSTRACT OF DISCUSSION.

Dr. Samuel J. Walker, Chicago: General paresis in childhood is, of course, extremely rare. About 70 per cent. of the cases in the adult can be traced to a previous syphilitic history, and in childhood, so far as I know, all the cases reported have shown a history of congenital syphilis. In childhood the type of the disease is purer, as many things that may creep into the cases in the third and fourth decade of life are practically excluded in childhood. Dr. Fairbanks said that he saw this case two years after the onset. Had the case been diagnosed as general paresis before he saw it? If not, what did the parents think was the trouble with the child and what was the diagnosis of the physicians who had seen it? As to the pupillary findings in the adult type—and it is almost necessary to speak of the adult type in paresis—one of the earliest somatic signs is partial or complete Argyll-Robertson pupil. This is one of the earliest and also most frequent signs. It is true that paresis and cerebral syphilis are usually the only conditions that have to be differentiated, but as the condition advances the case clears up as to diagnosis. Some years ago I saw a case of cerebral tumor not associated with optic atrophy. The mental symptoms were very like the symptoms in general paresis and not until the very last, when optic neuritis developed, were we even fairly certain of a diagnosis. The postmortem showed a tumor the size of an egg in the frontal portion of the brain.

Dr. Arthur W. Fairbanks, Boston: The case had apparently not been diagnosed before I saw it. The patient was brought to me at the Children's Hospital, and the parents probably had an inkling of the condition. The family history of the boy was what I think gave the mother an idea of what was happening. The father had died in an insane hospital with a diagnosis of organic dementia four months before the child was seen. The postmortem revealed diffuse arteriosclerosis including the basal vessels of the brain. It was not stated whether it was specific or not. In this case there was a perisplenitis and a perihepatitis. The mother gave no specific history as to rashes, miscarriages, etc., but the family physician stated that several years before she had come to him with an obstinate ulcer of the leg and two years later with iritis; neither trouble would yield to anything but the administration of potassium iodid. A sister of this boy is defective mentally and has an acquired strabismus. I think that there can be no question but that here we have a specific origin for this disease. The pupils were dilated markedly, and while one would slightly respond at first, later it became fixed and remained fixed for the rest of the child's life. I think that a tumor would have to be in a very peculiar location, as was Dr. Walker's, to confuse the diagnosis. It is true you do get the changed character, as in paresis, but you also get vomiting and an optic neuritis, which you do not get in paresis. Then the focal signs would point to a localized lesion of the brain. Occasionally, when the optic neuritis and vomiting are absent, it might for a brief time obscure the diagnosis, but not for long. In the synopsis I have here of these thirty-eight cases, all well within the period of childhood, you will notice the extreme family syphilitic history. It is very striking. Sometimes there is no outward evidence of stigmata in the patient. One should then examine the brothers and sisters, and examine the fundus as well as the external eye. Then one may find iritis or chorioiditis.

MERCURIAL TREATMENT FOR THE LATE MANIFESTATIONS OF SYPHILIS.*

HERMANN G. KLOTZ, M.D.

NEW YORK.

THE HISTORY OF THE TREATMENT OF SYPHILIS.

Syphilis had hardly been introduced into civilized Europe, when mercury offered a helping hand in the treatment of the new disease. As early as 1497 Gaspardo Torella, an Italian physician, recommended mercurial ointment. This early external application of mercury probably was not merely accidental, as some authorities would imply, but due to the fact that mercurial ointments had long been in use against all kinds of skin diseases, having been first introduced into practice by the Arabian physicians in the twelfth century. As the principal and most obvious symptoms of the new disease were pustules, ulcers and other lesions of the skin, it was quite natural that the customary remedies for skin diseases should be applied.

Following the reckless abuse of mercury during the earliest period, when the treatment of syphilis was not generally in the hands of the better class of physicians, the vegetable decoctions for a short time superseded it under the guidance of the knight-errant Ulrich von Hutten, who sang the praise of guajac. But soon mercury was again recognized and firmly established as the only and true specific of syphilis, a position which it maintained without difficulty from the middle of the sixteenth to the early part of the nineteenth century.

During the early periods the use of mercury was entirely restricted to external applications, mostly ointments, but also plasters and at times fumigations; about 1535 Pierre-André Mathiole initiated the internal treatment with the red oxid of mercury, but the medication per os did not become popular until towards the end of the sixteenth century. During the following century many new preparations for internal use were introduced, among them numerous secret ones; later Van Swieten's liquor, a solution of the bichlorid, gained much favor; the protoiodid, first recommended by Biett and much favored by Ricord, was widely adopted in the early part of the nineteenth century. Inunctions retained their place beside internal treatment, but were conducted in a much safer and more reasonable manner than in the beginning.

In the eighteenth century, following the unfortunate deception of John Hunter, the identification of the three venereal diseases, gonorrhea, chancroid and chancre, was responsible for another period of too ardent use of mercury, and there appeared a more decided antimercurialistic tendency, at first in Great Britain, later also in France and Germany. Adversaries of mercury had existed from the beginning, primarily, probably, on account of its influence on the salivary organs.

That external applications could produce salivation had been known to Teodorico of Bologna and Guy de Chauliac as early as the end of the thirteenth and the beginning of the fourteenth century. Probably owing to the usual coincident appearance of salivation with the marked improvement of the symptoms of the disease, soon the opinion began to prevail that salivation was really beneficial and, in fact, essential to a cure. This theory persisted almost without any contradiction until the end of the seventeenth century, when David Abercromby, in 1684, was the first to formally declare that salivation was not necessary to obtain the favorable effects of the drug. It was a long time before the old doctrine lost its hold on the medical profession in general, and it is by no means extinct now; one still meets in the periodical literature and even in text-books the hardly disguised or concealed opinion that a certain amount of salivation is more or less desirable or unavoidable and necessary during mercurial treatment. It surely is found frequently enough on patients with, but more commonly without, the beneficial effect on the disease itself. But besides the well justified dread of salivation there has always existed a not so well explained fear of some mysterious and mischievous power of mercury which would render it a most dangerous drug. In spite of the long-established fact that the symptoms of real mercurial poisoning are entirely different from those occurring in the course of syphilis, and in spite of the easily obtainable proof that mercury is more or less rapidly eliminated in measurable quantities in the urine, the saliva and the feces, there still lingers to-day, not only among the laity but even among members of the medical profession, the idea that mercury will remain indefinitely in the bones or somewhere else in the body. Many physicians who shrink with horror from the idea of administering one and a half grain of calomel by an injection, would not hesitate for a moment to prescribe one or even two ounces of iodid of potassium daily.

---

* Read in the Section on Cutaneous Medicine and Surgery of the American Medical Association, at the Fifty-ninth Annual Session, held in Chicago, June, 1908.

*The conclusions are based on practical experience, but the demonstration of the effects of mercury on the *Spirochæta pallida* and of the presence of the latter in the late products of syphilis apparently explain and justify the same in theory.

It was then quite natural that a constant search should go on for another, less objectionable, specific for syphilis. But all efforts had failed until in 1836 Wallace of Dublin introduced the iodid of potassium in the therapeutics of syphilis. Its success was remarkable; no objection whatever was raised to it and it was at once accepted with favor by the practitioners and generally approved by eminent syphilographers of that time like Ricord. The physician who had been afraid of mercury could now quiet his conscience by treating his patients with the new, apparently harmless, remedy. Not all the high expectations, however, were fulfilled; it soon became apparent that iodid could not entirely supersede mercury and that its best effects were obtained in combination with the latter.

THE LIMITATIONS OF THE IODIN TREATMENT.

I do not wish to enter here into a discussion of the much mooted question whether iodin has any really curative influence on the disease and its causative agent itself, or, as some authors believe, only disposes of the symptoms by promoting absorption of the pathologic products and by eliminating toxins. To be candid, we are, or at least we were until quite recently, in the same position with regard to mercury, but in the light of recent discoveries it seems highly probable that mercury has a direct restraining or destroying influence on the spirochete.

It soon became apparent that the later or so-called tertiary symptoms offered a more favorable field for the iodids than the early or secondary ones. I must say that in my own experience I often find iodid of great value in certain early conditions, particularly in some affections of the throat. This preference of iodid for the tertiary stage soon became widespread, and gradually the rule has crept in and has become more or less generally established that in the later stages of syphilis the iodids *are absolutely necessary for a cure, and that they alone* should be given and mercury be entirely discarded. This doctrine has all along been disputed and condemned by eminent students and men of great experience in the treatment of syphilis like Virchow, Ricord, Mauriac and, among others, by that industrious student of syphilis, the late Robert W. Taylor. Still, this arbitrary rule, as he called it, continues to be proclaimed by the authors of text-books; it is continuously met almost as beyond dispute in the periodical literature; and it is evidently almost generally followed in the daily practice of thousands of members of the medical profession. In fact, the belief is so deeply rooted in the mind of the majority that any attempt to throw doubt on its correctness will be looked upon as arrant heresy.

In general, the tertiary and gummatous manifestation of syphilis offer a much better criterion for the effectiveness of a certain remedy or method of treatment than the earlier, secondary ones, because, as a rule, they do not possess the inherent tendency to improve or to disappear spontaneously, which, to a certain extent, is present in the earlier, principally the more generalized, eruptions; they are rather progressive and increase or advance unless checked by treatment. The various late manifestations, however, show decided differences of character and development; ordinarily we associate with the gumma or the gummatous infiltration the more or less pronounced tendency of the newly formed tissues to break down and undergo degenerative changes, leading to absorption or to destruction.

There exist, however, later products of syphilis which do not have such a tendency, but are considerably persistent and resistant. I am not speaking of those conditions which now are usually designated as parasyphilitic, but of quite distinctly specific and substantial affections of various organs in which the prevailing tendency is to form new, rather firm, often almost sclerotic tissue. Such late syphilitic processes are observed in almost all viscera, sometimes side by side with really gummatous products, as in the liver, the kidney, the lungs, the adrenal glands; they occur in the testicles, in lymph glands, in the bony structures, preferably in the central and the peripheral organs of the nervous system, including the sensory organs, and finally in the blood vessels, not only of the brain, but also in the large trunks, in the arteries and probably the veins of the extremities and in small terminal vessels. In fact, the origin of all these products of syphilis seems to be ultimately connected with the blood vessels. The skin, the subcutaneous and submucous tissues, as well as the mucous membranes themselves, which furnish a large percentage of the secondary and also of the more common gummatous formations, are less frequently the seat of these more persistent formations; they may, however, appear here and on the bones in the shape of real tumors. There must also be mentioned the mostly unilateral, late scaly affections of the palms, soles and occasionally of other portions of the skin. All such cases present a more or less pronounced resemblance to similar conditions of entirely different origin; they therefore are liable to offer the greatest difficulty to the establishment of a correct and sure diagnosis. They frequently give rise to mistakes in treatment, particularly to the performance of not only unnecessary but absolutely harmful operations. The late Professor von Esmarch was candid enough to publish some years ago a report of a number of cases in which the syphilitic nature of the affection was recognized only after the operation and in some instances only after the recurrence of the growths. Naturally the patients under such circumstances are often submitted to the test of therapeutics, and on the result of the tentative treatment future proceedings will depend.

Now all lesions of this kind are more or less refractory to all treatment, but in the majority of cases they are not at all or but slightly affected by iodids alone, even in the large doses commonly given in our country; they are likewise resistant to the so-called mixed treatment. But the partisans of iodid will retort that they are not affected by mercury alone either. This, I freely concede, is true in regard to the methods of mercurial treatment heretofore principally in use. The pills of the protoiodid which seem to be the great favorite in our country, are practically inert in such cases. Solutions of the bichlorid, which are much less used than they deserve, and the mixed treatment may produce an improvement or an apparent cure, but mostly only a temporary one, soon followed by a relapse. Inunctions, even if made correctly and with all the accessories which are necessary to obtain the full benefit, are often enough ineffective, but much more so if they are made in the slipshod way only too common among patients who are not willing to change their often very unhygienic ways of living.

INJECTIONS OF MERCURIAL SALTS.

Mercurial treatment, however, has entered on an entirely new phase by the introduction of the hypodermic and intramuscular injections of soluble salts, and even more, of the insoluble salts and of the gray oil and similar substances. It might seem as if there could be but little difference in the therapeutic effects between the frequently repeated injections of soluble salts and the intramuscular injections of insoluble ones, made at longer intervals. It had been assumed that the latter furnish a deposit of mercury on which the organism gradually draws in small amounts until the deposit is nearly exhausted, when a new supply is furnished. But recent investigations, particularly those made under the auspices of Jadassohn by Emil Buergi of Berne,[1] have shown different conditions. It appears that subsequent to an injection an increased amount of mercury is at first eliminated in the urine and after about two days becomes reduced; evidently, then, during the first days following the injection a large amount of mercury must circulate through the blood so that we actually receive from the injection a single large dose of mercury, much larger than it is possible to introduce by any other method; and during a series of injections we have a number of such inundations of the entire system with the drug, a number of mercury storms, if you please. At the same time the entire amount of mercury consumed is much smaller than with other methods. For instance, if during the entire course of treatment within, say, two years, a patient receives altogether fifty injections of 10 centigrams of the salicylate of mercury which contains about 59 per cent. of metallic mercury, the total amount of the metal entering the body will amount to 2.95 grams, or about 47 grains. With calomel, which contains 84 per cent. of mercury, the total amount would be less than 68 grains for fifty injections, but ordinarily a smaller number would probably be required. Attention must also be called to the fact, so far not fully explained, that according to S. J. Meltzer and Auer,[2] the conditions of absorption in the muscle tissue are more favorable than in the subcutaneous tissue and very near to those of injections directly in the veins. The widespread use of these injections in Europe has certainly demonstrated beyond doubt that the human organism can stand much larger doses of mercury than formerly had been employed and that could safely be introduced through any of the older methods.

It has also been made evident that in many cases of syphilis such large doses are required in order to obtain the desired results, that conditions which heretofore had remained unaffected by any specific treatment and therefore had not been considered specific any longer, now have to be accepted as such. These facts have been insisted on by numerous authorities, principally in France by Leredde and others, and quite recently have led to the recommendation of a "plurimercurial" treatment by Jaquet,[3] consisting of the simultaneous administration on the same day of pills of the protoiodid by the mouth, Van Swieten's liquor by rectal injection, the intramuscular injection of one centigram of the biniodid and the inunction of two grams of blue ointment. These applications are to be repeated on several days in succession and to be taken up again after a more or less extended interval. Without commending such exaggerated treatment, I must insist that the intramuscular injections of insoluble salts have come into such general use all over the entire European continent and, if I am not mistaken, lately also in Great Britain, that an immense number of observations is in existence which prove that these energetic applications of mercury exert a much greater influence on the late manifestations of syphilis, not only on those which heretofore mostly yielded to iodids alone or in combination with mercury, but also on those more solid formations of which I have spoken before. The practice of these injections is now and has been for years so common that one hardly finds now any special articles on the subject, but whoever peruses the current literature, even to a moderate extent, will meet numerous examples of cures effected by injections when iodids and inunctions had failed, even in the hands of experienced men, particularly in cases of affections of the nervous centers.

To mention only a few recent publications, in a paper on "Experience with the Treatment of Disturbances of the Nervous System on a Syphilitic Basis," by W. Harttung and O. Förster[4] of Breslau, the former reports cases of paralysis, etc., the latter cases of incipient tabes; and V. Mucha, from the clinic of Finger, in a paper on "The Differential Diagnosis Between Lues and Tuberculosis in Ulcerative Processes,"[5] reports several cases in which injections of the salicylate effected sufficient improvement to assure the diagnosis of syphilis which the histologic examination had not been able to clear up. It is, however, almost generally agreed that the most energetic action is obtained from the injections of calomel.

I must mention also a paper which was quite recently published in this country on "The Diagnosis and Treatment of Syphilitic Lesions of the Nervous System,"[6] by T. H. Weissenburg of Philadelphia. He says:

> It has been my experience that, whenever any benefit has been obtained, it has been the result of the use of mercury and not of iodids. Even in the specific manifestations which come on many years after the infection, mercury is the only drug which will be of benefit. Iodids probably do good, and should be given in conjunction with the mercury, or, better still, after the mercurial treatment.

It is hard to understand why it should be given at all, if mercury, as stated, is the only drug which is of benefit; the recommendation can be explained only as a concession to the prevailing popular sentiment in favor of the iodids, although it seems that many physicians consider it necessary to follow up every administration of mercury by a course of iodids in order to get rid of the mercury as quick as possible—evidently another consequence of that deadly fear of it. I must not omit to mention that Weissenburg recommends the use of inunctions, but I have no doubt that he would be glad to use the insoluble injections if he would only try them in spite of the prejudices against them in America.

My experience with intramuscular injections agrees with that of others who have learned to trust to mercury in the late manifestations. I have used them constantly for about twenty-five years, and after giving a report[7] on the first two hundred injections in 1889 have applied them more and more within the last years, after an extensive previous experience with soluble preparations, the bichlorid and the bicyanid. Several times I have been tempted to return to soluble injections like the strong solutions of the bichlorid as recommended by Lukasiewicz, which were extremely painful and caused much local swelling, solutions of the oxycyanate, mercury salicylarsenate, etc., but I have always quickly returned to the insoluble ones, which I find acting more favorably and having fewer objectionable features. Encouraged by the excellent results in the earlier stages of syphilis, I began to use the injections in the later manifestations when the iodids or the mixed treatment gave results which were unsatisfactory, or as was more frequently the case, not lasting, particularly in the tubercular syphilides. My experience has gradually induced me to trust to the injections alone much more than to the iodids, and I have more and more dispensed with the latter, without, however, giving them up entirely.

I shall not attempt here to give any detailed or specified histories of cases. I shall only state briefly that in the course of years I have treated with injections of the salicylate and to a certain extent of calomel the most various manifestations of syphilis, not only the more frequent gummatous affections of the skin and of the mucous membranes but periostitis and tophi of the cranial and other bones, at times in a condition when a breaking down of the integument seemed unavoidable, affections of the nervous centers and of the eyes, particularly iritis, paralysis of the muscles, neuritis optica, usually at the instance and under the supervision of ophthalmologists, gummata of the tongue and of the lips, swellings of the lymph nodes, gumma of the testicle, late scaly affections of the skin, among them one which appeared on the fingers of the right hand after eighteen years and finally yielded only to calomel injections, gumma of the muscles and syphilitic arteritis. The results at times have been really marvelous, exceeding my keenest expectations; usually very satisfactory; and seldom actually disappointing, although I am far from claiming that the injection will be successful in all cases. In many instances I have been able to watch the further progress of the patients for years, and I have never observed any disastrous or even disagreeable consequences.

The injections of calomel have been the particular object of abhorrence to the adversaries of the insoluble injections. In fact, they are more liable to cause some local inconvenience; circumscribed subcutaneous swellings or nodules, as a rule painful only on pressure, are not so rare as after the salicylate, but these swellings have not the tendency to break down or to leave any outward marks; the general symptoms, slight malaise or fever, usually appear in a slightly more aggravated degree, somewhat later than after the salicylate and of longer duration. In a large number of cases, however, the general and local effects were not aggravated and at times entirely absent.

In some instances I have indeed found a greater tolerance of calomel than of other preparations. Thus, in two cases in which the injections of the salicylate caused diarrhea with tenesmus, calomel did not cause the slightest disturbance of the bowels, although in the one case a large quantity of sugar was present in the urine. In a case of a chronic albuminuria, soon after an acute exacerbation of an old nephritis which antedated the syphilis infection, the albumin entirely disappeared during the treatment of a gumma of the testicle with calomel injections. I have felt encouraged to make these perhaps somewhat hazardous trials by the confidence which long experience has created, but I do not advise others to repeat them until they have obtained sufficient experience and know all the safeguards.

The intramuscular injection of the insoluble preparations from the begining have in this country met a widespread and bitter opposition which must remain unaccountable to anybody who has approached the new treatment without bias and has tried it for a reasonable time. As a rule the physicians of our country are by no means averse to taking their cue from European teachings; on the contrary, many things in theory and practice are accepted and adopted solely on the strength of their European origin and recommendation. Still, this method which has been practiced in all the countries of the European continent for more than twenty years, which has become the favorite and is recognized as the most efficient one by almost all syphilographers of renown, is hardly mentioned or is peremptorily condemned and depicted with such horrible colors by the authors of textbooks and prominent teachers in colleges and universities, that students could hardly help considering its use almost a crime.

What will such students think of their teachers if across the street in a dispensary they find younger men using insoluble injections without fear and with excellent results, or if going to the European centers of teaching they see the intramuscular injections universally employed and acknowledged without dispute as the most efficient treatment? It certainly seems to be the duty of teachers to give to such a treatment a sufficient, unprejudiced trial, preferably in a hospital under careful observation, before condemning it as unscientific, mutilating, ineffective and dangerous to health and life. Still at last year's meeting several men who strongly opposed this treatment have directly stated that they had never made an injection of an insoluble salt. Of course, each man is responsible for his actions to his own conscience, but by the failure to apply other well-known methods if the usual ones fail, he deprives his patients of the benefit of a treatment which has long ceased to be an experiment.

---

[7] Jour. Cutan. and Genito Urin. Dis., 1890, vii, 41, 98.

I can not permit a method to be called unscientific which employs the smallest amount of mercury to obtain the greatest results, a method in which you know exactly the amount introduced and in which you may trace within a few weeks up to 30 per cent. and more in the urine, a method in which every bit is actually absorbed and in which the conditions for absorption are favorable. Or does anybody mean to assert that the inunction method is more scientific, when we not even know exactly whether the mercury is principally introduced through the skin or through the lungs? I cannot admit that because among hundreds of thousands of injections in a few cases several local troubles have occurred, the injections are mutilating. The worst result I have ever seen was a superficial circumscribed gangrene of the skin and subcutaneous tissue which I have conscientiously reported,[8] without being able to explain its immediate cause. I have only once since the first three months had any abscess after I had begun to make the injections. That was in two dispensary cases in which probably the injection fluid was at fault, for after throwing it away no other abscesses followed. Even when they occur, as a rule, they are aseptic, and not very acute or very painful. In contrast to the frequent affections of the oral cavity and the gums during internal treatment, inunctions and soluble injections, the almost entire absence of salivation and of every disturbance of the gums, particularly during salicylate injections, has always been a great and pleasant surprise. It has been one of the most cogent reasons for the now almost regular employment of the treatment. I have nothing more to say on the subject of the efficiency of the treatment.

As to the dangers resulting to health and even life, I admit that under exceptionally unfavorable conditions the intramuscular, insoluble injections are liable to become the cause of death in the very same degree as soluble injections, inunctions, fumigations and internal administration, applied with all necessary and known precautions. Cases of fatal consequences of all these methods can be found recorded in literature, but since the method has been better understood than it was in the beginning, not more frequently after insoluble injections than after treatment with the soluble salts.

Two accidents, however, are likely to occur: diarrhea (colitis) with tenesmus, and embolism of the lung. I have had experience with both, and, while I admit that they are very annoying complications, they are not really dangerous and do not permanently impair the health. The intestinal symptoms at times seem to be due to an incidental indigestion or neglect of common rules of diet, but usually appear as the effects of idiosyncrasy after every injection, even in reduced doses. The peculiar experience with calomel I have mentioned before. The trouble rarely lasts longer than twenty-four hours; it occurs oftener after the bichlorid and the oxycyanate than after the insoluble salts. I have published my experience with embolism of the lung[9] in 1898; since then I have seen only a few more. None of the patients was seriously sick at any time, they all recovered in a few days without any further trouble. I do not believe that embolism can be entirely avoided even with all the precautions that have been advised, like the removal of the syringe before injection. Altogether, I have long come to the conclusion that the beneficial effects so far outweigh the disadvantages that I am willing to take so much risk for the benefit of my patients, and I have usually found the patients ready to do the same thing.

It has been mentioned as a drawback that the patient has to be seen by the physician more frequently. This objection applies much more strongly to the soluble injections which have found so much favor with some men who so strongly object to the insoluble ones. I believe that the necessity of regular visits is rather an advantage. It certainly is not safe and correct to allow a patient to continue internal treatment or inunctions indefinitely without regular observation by the physician, as is quite often done. Soluble injections are generally quite painful immediately after the application, for one-half to two hours, are made every day, while the seat of the insoluble ones is really painful only on pressure or during movement for about thirty-six hours. The best proof that the patient does not suffer so cruelly as has been asserted is the fact that some have been perfectly willing to stand from fifty to sixty injections. As a rule, I have found patients neither cowards who were not willing to stand some discomfort or even pain, nor such fools that they did not recognize the advantages and the conveniences of the method.

CONCLUSIONS.

The following conclusions embody the points which I wish to emphasize:

Tertiary or late manifestations of syphilis can usually be as successfully treated by mercury alone as by iodids alone or in combination with mercury. In many instances they are influenced by strong mercurial methods when iodids and mixed treatment have failed. It is therefore advisable, in clearly syphilitic manifestations, not to cease specific treatment, and in doubtful cases not to dismiss the diagnosis of syphilis until such strong mercurial treatment has been sufficiently applied as offered by the intramuscular injections of insoluble mercurial preparations, of which calomel is the most reliable one.

These statements I do not ask you to accept without your own investigation; I ask you to subject them to a fair and unbiased trial. I am well aware that not all such cases of syphilis come under your observation, but that some are in the hands of general physicians or surgeons or of specialists, particularly neurologists, laryngologists, ophthalmologists and others, and that my statements ought to have been made before a general medical audience. It seems to me, however, that general practitioners as well as specialists will look for their guidance to those who make syphilis a subject of their special studies, and that they are not likely to adopt a treatment until it has been approved or at least has been brought to the knowledge and laid before the judgment of the syphilologists.

The conclusions are based on practical experience, but the demonstration of the effects of mercury on the *Spirochæta pallida* and of the presence of the latter in the late products of syphilis apparently explain and justify the same in theory.

130 West Fifty-eighth Street.

ABSTRACT OF DISCUSSION.

Dr. J. M. King, Nashville: I think we fail many times to relieve severe and malignant cases in the late stages of syphilis, because we do not use our remedies, particularly mercury, in sufficient quantity or with sufficient energy. Fournier certainly impresses this on us in his late text-book. I recently saw a very malignant case of syphilis in a man who evidently furnished fresh soil for the disease. He had received internal treatment for two years, during which time he visited Hot Springs twice, but still his lesions failed to heal. He had developed a severe glossitis with a generalized skin eruption two years after the initial lesion. He also had a hard lesion on the glans penis, and a granulomatous lesion on the calf of one leg. Large doses of iodid had failed to relieve him. I gave him seven calomel injections, in doses of 5 centigrams, injected deep into the gluteal region, and afterward substituted gray oil. Under this treatment his skin eruption practically cleared up, and the gummatous lesion on the right calf is almost healed. While the injection treatment is certainly the most efficacious method of treating syphilis, there is one objection to the use of calomel, namely, it is liable to produce pain and tenderness and even abscess at the site of the injection unless it is injected deep into the muscles.

[9] Arch. f. Dermat. u. Syph. xliii, Festschrift, für Pick., 1898, p. 407.

DR. JOSEPH ZEISLER, Chicago: The remarks made at the meeting of this section a year ago by the late Dr. Robert W. Taylor were rather denunciatory of the use of insoluble injections in general. I then warmly defended soluble injections and opposed the use of the insoluble salts. It is therefore only fair that I should now be permitted to express my change of front since that time. I was impressed by Dr. Gottheil's paper on this subject at our last meeting, and after an exchange of ideas with him, I began the use of injections of salicylate of mercury about eight months ago. Since then, after having given several hundred of these injections, I have been perfectly delighted with them. In certain forms of deep-seated tertiary lesions I was able, by means of injections of the insoluble salts, to produce results far superior to those of any other method of treatment that I had hitherto tried. I recently saw a young physician, a former pupil of mine, with mucous lesions and other evidence of an old syphilis. He objected to the proposed use of injections of salicylate of mercury, and when I expressed my surprise at this, he said that he had read my remarks on the subject made a year ago. I told him practically what I have said here to-day and explained my change of view, as I had already done on a previous occasion, at a meeting of the Chicago Medical Society. He still objected to the injection method, and I thereon refused to treat him. The following day he returned and made no further objection, and after the third injection the mucous patches on his tongue had disappeared, and my young friend had become very enthusiastic in regard to the treatment. In his case, only four or five injections were necessary. Many of you who at the present moment are opposed to the use of the deep injection of the insoluble salts of mercury in syphilis do not, I venture to say, even use the soluble ones. I believe that if you will take up the method and familiarize yourself with its technic, which is extremely simple, you will soon become as enthusiastic in regard to it as are Dr. Gottheil and Dr. Klotz.

DR. M. L. HEIDINGSFELD, Cincinnati: I have used a preparation of lanolin and metallic mercury equal parts, by weight, with very gratifying results for a number of years, and it has also been employed by a number of confrères, including Dr. L. E. Schmidt of Chicago and Dr. Eugene Hay of Hot Springs. I have never given a larger dose than 3 grains, but Dr. Schmidt has given as high as 5 grains of metallic mercury to each injection. Its results are especially shown in the very severe and persistent forms of eruption affecting the mucous membranes. The average case of syphilis will take care of itself, but some of these persistent cases are the ones wherein the injection treatment has been most gratifying. I recall the case of a man of 32 who came to me during the past year from Savannah, Ga., with the history of an epithelioma of the penis. The lesion had originally been regarded as syphilitic, but as it had failed to improve under the internal administration of mercury and the iodids, the penis was amputated. When I saw him, eighteen months later, there was a supposed recurrence. This entirely cleared up after a few injections of the insoluble salt in large doses, which proved the case to be one of syphilis without a doubt. The chief advantages of the preparation are the stable character, large dosage and great tolerance.

DR. W. H. DAVIS, Denver: At the time of the last meeting of the section I had been using injections of the salicylate of mercury. Subsequently I began the use of gray oil, and from the latter I have not had the painful indurations and infiltrations that I had when I used the salicylate. I regard gray oil as the best preparation I have used. I am sure that if you will take up the use of gray oil in accordance with the technic of Dr. Gottheil, the good results you will obtain will be a revelation to many of you.

DR. EUGENE CARSON HAY, Hot Springs, Ark.: Up to two years ago I used the soluble mercurial salts entirely for injection purposes. The bichlorid I never used, on account of the pain to which it gave rise. About two years ago I began the use of the salicylates of mercury, and while my results have been good, I think that perhaps we are apt to become too enthusiastic in regard to it, and forget the equally brilliant results that may be obtained by the older methods. I am still a believer in the ordinary routine treatment of syphilis, and my experience with the inunction method especially has been very favorable. If we take, for example, one hundred cases of ordinary secondary syphilis, and give the patients inunction treatment, and then take a second hundred and treat them by injections of the insoluble salts, I venture to say that the lesions in the first hundred will clear up just as rapidly as those in the second hundred; in other words, that the results of one method of treatment will be just as good as those of the other. Of course, there are exceptions. Some individuals apparently do not get the effects of mercury when given by inunction, and in such cases the injection method can be substituted. Frequently the first symptom produced by mercury is its depressive effect on the nervous system, and the gums are not an infallible guide. I saw a man recently who received sixty inunctions of mercury without any effect, and who rapidly improved with the substitution of the injection method. I gave up the use of the insoluble salicylate of mercury entirely about six months ago, because so many patients complained of the pain produced by the injections, and have been using the modified gray oil ever since. This modification I learned of through a conversation with Dr. Heidingsfeld about three years ago. He told me about a combination of lanolin and bi-distilled mercury that he was using, and sent me a loaded syringe, requesting I give it a trial. I am pleased to state that his modification of Lang's oil gave rise to less pain than any other preparation of mercury that I have ever employed, and the results have been generally very gratifying. In severe or malignant cases of syphilis, where a rapid effect is desirable, I prefer the injection treatment, but in the ordinary run of cases I can accomplish just as much with the inunctions. In syphilis of the nervous system I look on injections as the best method of treatment.

DR. WILLIAM A. PUSEY, Chicago: I appreciate the value of testimony such as Dr. Klotz has given us in regard to the use of insoluble salts, and in extreme situations I fully approve of the adoption of injections of mercury; but I prefer to give mercury by the mouth rather than by the muscles, for the same reason that I prefer to give nourishment by the mouth rather than by the rectum; and so long as a patient can take it by the mouth and be benefited thereby, I see no reason against that method of administration in the majority of cases. Whenever I listen to a discussion of this kind, emphasizing the ease and efficacy of these newer methods, I wonder if my experience with syphilis has been more fortunate than that of most men. The ordinary case of syphilis, in my experience, is one of the easiest things to treat. All the patient requires is rational and specific treatment. The administration of mercury and potassium iodid is an extremely simple proposition, as a rule, and the cases of syphilis requiring the new methods of treatment are extremely rare. As to parasyphilis, nobody knows the relative frequency of parasyphilitic manifestations after any particular form of treatment, nor does it appear that any form of treating syphilis has any effect on the subsequent possible development of tabes or general paresis. It has not been proved that those diseases are due to the virus of syphilis, and it is more probable that they are due to some of the antibodies of the disease. I do not wish to combat the use of the injection treatment of syphilis in those cases in which heroic treatment is indicated, but I do think that somebody should say a word in favor of the extreme amenability of syphilis to the ordinary methods of treatment.

Dr. Henry Clay Baum, Syracuse, N. Y.: Dr. Pusey expresses my views in regard to the proper method of treating syphilis. I employ both soluble and insoluble injections, but only on rare occasions and not as a routine. I believe that if one thoroughly masters any particular method of treating syphilis, and at the same time studies the needs of his patients and keeps them in good health otherwise, he will be successful, whether he employs the injections, inunctions or gives his drugs internally. In rare cases, any particular method may fail; and then a change to another is necessary. In my experience with syphilis, extending over a quarter of a century, I have no apologies to offer for the methods employed—usually internally medication and inunctions. I am inclined to believe that the later manifestations of syphilis are not due to the failure of the method of treatment, but to the fact that the patient was inadequately treated during the early stages of the disease.

Dr. M. Lyon, DeWitt, Iowa: I notice that nobody has said anything about the intravenous method of injecting mercury, as recommended by Dr. G. Frank Lydston in The Journal, Nov. 16, 1907. I have treated several patients by intravenous injections of bichlorid of mercury. The injections gave rise to considerable pain, which, however, disappeared rapidly. The preparation I used was a 1 per cent. bichlorid solution, injected directly into the vein. By this method quick results will be obtained in desperate cases—sometimes inside of twenty-four hours.

Dr. David Lieberthal, Chicago: I have employed injections of bichlorid, gray oil, calomel and salicylate of mercury in the treatment of syphilis for the past fifteen years. I also use other modes of administration. Whenever I am convinced that a patient will carry out instructions, I prefer the inunction method because I consider the same the treatment par excellence. When difficulties arise for its application, the injections are the next choice. Any one employing them must be impressed by their marked effect. Among others, I recall a case of acute iritis, which cleared up within forty-eight hours after a single injection of salicylate of mercury. If a syringe with a leather or rubber washer be employed, care should be taken that the washer be in good condition, because the leather or rubber readily decomposes and particles may be carried with the injection fluid into the tissues and cause abscess. As a menstruum for insoluble preparations, olive oil is preferable to liquid petrolatum, because the latter is apt to produce harder infiltrations and of longer duration. The injections of insoluble salts should rather be applied hypodermically than intramuscularly, because if an abscess should form, it is more easily accessible. In tertiary manifestations, we should combine the administration of potassium iodid with mercury. After the symptoms have subsided, a prolonged course of mercurial treatment should follow, in order to prevent a recurrence of tertiary lesions.

Dr. M. B. Hartzell, Philadelphia: I have never resorted to the insoluble injections of mercury. The use of the insoluble injections, as admitted even by the advocates of that treatment, is oftentimes followed by disastrous results. Millions of men and women have been successfully treated with mercury given by the mouth. I believe that there are urgent cases of syphilis in which the hypodermic method of treatment is indicated, but in those cases the use of the soluble salts will accomplish quite as much as the insoluble. After you have injected an insoluble preparation of mercury into your patient, it is beyond your control, and you do not know how long it will take to absorb it. Those who assert that the insoluble preparations are more efficacious than the soluble attempt to prove too much. They state that the insoluble mercury is gradually and slowly absorbed, and that the patient is gradually placed under its influence. With a soluble preparation, the effect will continue until the drug is absorbed; with an insoluble preparation, you do not know what will happen. I am opposed to depositing mercury in a man's tissues, since you are absolutely incapable of knowing whether it will be absorbed in a few hours or a few weeks. In the vast majority of cases of syphilis, I believe that this method of treatment is unnecessary. It is easy to say that the patient does not object to the treatment, but I am quite sure that most of us, if we had to take mercury, unless there was an urgent necessity, would prefer to take it by the mouth. In my opinion, the intravenous method of injecting mercury is little short of criminal.

Dr. Hermann G. Klotz, New York: I came here on account of the adverse and harsh remarks on the injections of insoluble mercurial preparations which had been made at last year's session, and I had looked for considerable criticism of my paper. I did not particularly mention the gray oil, because I have had hardly any experience with it; I do not believe in having too many irons in the fire at the same time; but if I find a method a good one I study that thoroughly and try to master it. I had regarded gray oil as a valuable remedy in syphilis until recently, when I read papers by Welander and by Zieler, the latter an assistant of Neisser, which really were intended to favor and to recommend the gray oil. But they actually gave me the impression that in its application it is more dangerous and less effective than the salicylate and calomel, because it is more liable to remain for a long time unabsorbed at the seat of the injection. In its action it is apparently more slow and more like the inunctions. I agree with Dr. Pusey that you can treat a recent case of syphilis more or less successfully by almost any method. It is justifiable to try the mildest remedies in the beginning, but if you are confronted with gummatous lesions of the integument or of the mucous membranes that are on the point of breaking down, or with an affection of the nervous system threatening paresis or death, or if you have to deal with a syphilitic iritis, with the eyesight of the patient at stake, then you have no right to delay or to try to temporize. There you have to act quickly and energetically; it is to such cases I have principally referred. If any one present has been so fortunate as not to have seen such cases in the course of his practice, I think that he ought not to oppose the methods of those who have been less fortunate. I can not regard the inunction method of treatment as more scientific than the injections, and it is inapplicable to many patients who can not give up their business. Several speakers have referred to the disastrous results of the insoluble injections. If there are any such results, I should like to have them pointed out and described. I have candidly published all the disagreeable occurrences which I have seen; they were limited to a number of cases of pulmonary embolism, the effects of which were transient in character. When mercury is injected into the muscles, it is no more within or beyond our control than when it is given internally or by inunction. By the latter method nobody can say how much or how little of the drug is absorbed, and when administered internally, we never know how much is taken up by the system, how much remains in the stomach or in the intestines, or how many pills pass unchanged through the intestinal tract and out again.

Norwegian-Danish Translation of Essay on Tuberculosis.—The essay of Dr. Knopf on "Tuberculosis as a Disease of the Masses, and How to Combat It," has been of great service in the crusade against the "Great White Plague." It has been translated into about twenty different languages, and in some cases two translations exist in the same language, as, for instance, an Italian and Russian. We have just received a translation into Norwegian-Danish by Dr. A. C. Amundson for use among the Scandinavians of this country, among whom the death rate from consumption is very high, higher than in the mother countries. The book is published at a low price, 25 cents (to physicians, 18 cents, postpaid) by the Amerika Publishing Company, Madison, Wis. This edition should receive a wide circulation among Scandinavian readers.

NON-SUPPURATIVE INVOLVEMENT OF THE LABYRINTH IN THE COURSE OF MUMPS.

REPORT OF TWO CASES.*

G. W. BOOT, M.D.
EVANSTON, ILL.

Mumps is ordinarily a disease of so mild a character that but little note is taken of its complications aside from the consideration of orchitis. The complication discussed in this paper, while not so common as orchitis, is much more serious as concerns function. The cases I purpose to discuss are those in which the labyrinth is involved in the course of mumps, not by a suppurative process, nor by the extension of a middle-ear process to the labyrinth, nor by the extension of an inflammatory process in the vicinity of the ear, but apparently by metastasis or by a primary localization of the disease in the labyrinth.

I have found in the literature reports on forty-nine cases that seem to me to fulfill these conditions. To these I wish to add the following reports of cases. The first is one which I examined with Dr. Shambaugh in the Central Free Dispensary:

Patient.—T. T., Greek, aged 21, single, occupation shipping clerk.

History.—Four weeks before his attack he worked with a man who had mumps. Three or four days before the onset of the ear trouble he had swelling at the angle of each jaw. These swellings were sensitive to pressure and caused considerable discomfort when he ate sour pickles. About the time of the onset of the ear trouble he had swelling of the left testis. On arising in the morning he noticed that he had a severe whistling of indefinite pitch in the right ear. At the same time he had vertigo which persisted. There was no nausea or vomiting.

Examination.—Both drum membranes were normal with the exception of slight thickening. The whispered voice was heard normally in the left ear, but not heard in the right ear. The Weber test (made by placing a tuning-fork in the median line of the skull) was lateralized decidedly in the left ear. Bone conduction was of normal duration. The Rinné test was positive in the left ear; that is a vibrating tuning-fork which was no longer heard when placed against the side of the skull or over the mastoid was still heard when held close to the auricle of the normal ear, but negative in the right ear; that is, the reverse was observed. There was apparently total deafness for the entire scale in the right ear.

The history of the following case was given me by Dr. Shambaugh, who had examined the patient in his private practice.

Patient.—H. G., female, aged 12, with no history of previous ear trouble.

History.—On the first day of an attack of mumps she noticed ringing and deafness in the left ear. Examination two months later showed both drum membranes normal; there was apparently no hearing for any part of the scale in the affected ear. The child was confined to bed for two weeks subsequent to the onset of the attack of mumps, during which time she was said to have suffered from "bilious fever," a diagnosis which was made apparently on account of the severe dizziness and vomiting, which were marked during that period. At the end of that time the dizziness and vomiting disappeared, but the patient was very weak. Since then there has been no noticeable disturbance of equilibrium.

SUMMARY OF REPORTED CASES.

In reviewing these fifty-one cases the following facts are observed: The ages of the patients ranged from 4 to 41 years, the greatest number of cases (thirty-one out of forty-four) occurring between the ages of 11 and 30. The average age was 18 years. Arranged by decades they were as follows:

	Males.	Females.
1 to 10	1	5
11 to 20	11	9
21 to 30	4	7
31 to 40	3	4
41 to 50	1	0

In all there were 22 males and 27 females. The condition of the middle ear was normal in 23, nearly normal in 4, abnormal in 3. These 3 were not abnormal as the result of this complication. Of the 21 cases in which the state of the drum membranes was not given it is reasonable to suppose that most of them were normal. In the cases in which the tuning-fork tests were given there were no indications of middle-ear involvement.

Mygind gives mumps as the cause of deaf-mutism in 3 per cent. of the cases occurring in Saxony and in 5 per cent. of the cases occurring in America. Bliss reported one case out of 282 cases of acquired deaf-mutism examined by him as due to mumps. Hinton says that *next to scarlatina, mumps most frequently* impairs the hearing. Buerkner gives mumps as the cause of 2 per cent. of the cases of labyrinthine deafness seen in the Göttingen clinic. What proportion of these cases were cases of labyrinthine deafness of the type under consideration I do not know.

The time of the onset of the labyrinthine involvement has varied from four days before the appearance of the parotid swelling to fifteen days afterward. If the case is excluded in which the labyrinthine involvement was said to have occurred four days before the parotitis, the average time of the appearance of the labyrinthine involvement is seven days after the onset of mumps.

The mode of onset was given in 23 cases as follows: Sudden in 6, rapid in 16, gradual in 1.

Of the symptoms indicating labyrinthine trouble, vertigo is present in 29, absent in 7, and not stated in 15. In the cases in which it is not mentioned it is probable that it was not a distressing symptom or it would have been mentioned. In some of the cases it was a very annoying symptom and is described as severe. In one case the patient fell at the moment of attack as if struck. In another there was an irresistible tendency to fall forward. In another the patient could not walk because of the intense dizziness.

Headache was mentioned in but 10 cases. In 6 it was present and in 4 absent. In none does it appear to have been a troublesome symptom. Nausea and vomiting are mentioned in 22 cases, as follows: Nausea with vomiting in 4, vomiting in 15, vomiting absent in 3. Fever was noted as being present in 3 cases. Unconsciousness is noted but 5 times. It was present in 3 cases and absent in 2. It was probably absent from all the cases in the series except the three in which it was specifically stated to have been present.

Subjective noises were noted in 26 cases. In 25 they were present and in 1 absent. They were unilateral in 3 cases and in 2 of these they were on the right side. The noises were noted as being loud, violent or severe in 7 cases. In the other cases their type and severity are not given.

The labyrinthine involvement was bilateral in 10 cases and unilateral in 32 cases. Of the unilateral cases 15 were on the right side and 14 on the left side. The gait was noted as normal in 3 cases and in 11 cases was described as reeling, drunken, uncertain, staggering or bad.

---

* From the Ear Department of Rush Medical College.

TABLE OF CASES OF MUMPS COMPLICATED BY NON-SUPPURATIVE INVOLVEMENT OF THE LABYRINTH.

Observer	No. of Case	Age	Sex	Middle Ear	Stage	Mode of Onset	Vertigo	Headache	Vomiting	Fever	Unconscious	Subjective Noises	Unilateral	Bilateral	Gait	
Connor	1	Adult	F	Not Normal	Late	Sudden	+		+				R		Staggering

“	35	19	M	Normal	6th da	Gradual	+		Nausea				L			Was dizzy and nauseated the day before parotids swelled.
“	36	35	M	Slight Changes.	10th da		+					+	L			Dizzy on 3rd day. Tended to fall backwards on 10th day.
Dempsey	37	17	M	Normal	6th da	Rapid	O	O				Loud	R			Weber to the left. No improvement.
Foster	38	4	M	Normal		Rapid	+		+			Marked				Fell at onset. Deaf during course of mumps.
Lake	39	35	F	Normal	7th da	Sudden	+	O	Nausea				L	+		No forks heard on left side by air conduction.
Crockett	40	9	F	Normal	14th da	Rapid	O	O				+		+		No ocular disturbances. One year later heard 40 v. s. fork only.
“	41	16	M		Late	Sudden	+		+			Violent	L			Deafness in left ear total in 1 hour. Nausea and vomiting for three weeks.
Haug	42	11	F			Sudden	+		+	+				+	Uncertain	Deafness occurred 4 days before the parotitis. Occipital pain at onset.
Brieger	43				12th da			+	+	+						
Urbantschitsch	44	12	F		14th da		+	+	+		O	Intense				Slow pulse. Onesided weakness of lower limbs.
Lake Reported by Hall	45	35	F	Normal	7th da	Sudden	+		+			Severe	L			Occurred in a hereditary deaf mute. Lake considered it due to thrombosis of a branch of the internal auditory artery.
Hall	46	17	F										R			
Alt	47	40	M	Normal	3rd da		Severe					+	L			Occurred immediately after mumps. Left sided mumps. Hearing improved so that a whisper heard at first at 1 meter was heard at 5 meters. Looking upwards or arising from a horizontal position caused intense dizziness.
Alt	48	22	F	Normal	3rd da		Severe					+ R	R		Uncertain	Right sided mumps. Could not walk for dizziness.
Burnett	49	Adult	M				+					+ L				Left parotid swollen first, 4 days later right, 4 days later left testis, 4 days later right testis, 2 or 3 days later right sided pleurisy. *Apparent motion of* objects toward the left. Tends to fall to the left. Has coppery taste in the mouth when dizziness is increased from any cause.
Boot	50	21	M	Normal	3rd da		+		O			+ R	R			
Shambaugh	51	12	F	Normal	1st da		+		+			+	L			Orchitis developed at time of ear involvement.

+ =present. O=absent.

ETIOLOGY.

Although a number of these patients had orchitis there seemed to be no relation between the orchitis and the labyrinthine complication other than that they both occurred in a disease of a type in which metastatic involvement was common. There seems to have been no relation between the side of the face involved in the mumps and the ear involved in the labyrinthine complication. Neither was there any relation between a unilateral or bilateral labyrinthine disease other than that already mentioned, that they occurred in a severe type of the disease.

There are three distinct types of labyrinthine involvement in the course of mumps. They are:

1. Involvement of the cochlea chiefly.
2. Involvement of the semicircular canal system chiefly.
3. Involvement of both cochlea and semicircular canals.

The first type is seen in Case 19 of this series in which a girl of 19 with normal drum membranes lost the hearing of the right ear in the course of twenty-four hours on the third day of an attack of bilateral mumps. There was no vomiting, dizziness or disturbance of gait and no recovery of hearing.

The second type is seen in Case 47 in which a man of 40, with normal drum membranes, was taken with severe dizziness, subjective noises and moderate left-sided deafness on the third day of an attack of mumps. In this case a whisper which at first was heard in the affected ear at one meter, after treatment was heard at five meters.

The great majority of cases fall under the third class in which both cochlea and semicircular canals are involved in varying degrees at about the same time. This is to be expected if the anatomic relationship of the parts involved is considered.

Case 44, reported by Urbantschitsch, is particularly interesting. It occurred in a congenital deaf-mute on the fourteenth day of an attack of mumps. The patient became unconscious. She suffered from vertigo, headache, vomiting and intense subjective noises. Later she was found to have lost the small amount of hearing that was present before the attack.

PATHOLOGY.

The pathologic anatomy of this complication has not yet been worked out. I have not been able to find any report of postmortem examinations of this complication of mumps. Reasoning by analogy from postmortem findings in labyrinthine disease from other causes it seems certain that this complication is not due to pyogenic organisms. It is not due to an extension of a middle-ear inflammation. Thrombosis of a branch of internal auditory artery, hemorrhage into the labyrinth, and acute neuritis of the auditory nerve may be present, but judging from the absence of similar conditions in other parts of the body in mumps they do not seem likely causes of the labyrinthine affection. It seems to me likely that the trouble is an acute infection by some non-pyogenic micro-organism, probably the streptococcus described by Bein, Michaelis and Busquet as the cause of mumps, and that it reaches the labyrinth by way of the blood, causing an inflammation that may reach any grade short of pus formation. In some of the cases in which hearing improved considerably under treatment the inflammation could hardly have been more than a serous effusion into the labyrinth. In most of the cases it must have reached a grade severe enough to have caused destruction of the delicate structures of the organ of Corti and of the sensory mechanism of the semicircular canals and vestibule. This type of inflammation is in accord with that seen in the parotid, where there is serous effusion with some cellular infiltration.

The following may be considered as descriptive of the symptoms of a typical case of this complication. About the seventh day of an attack of mumps, but possibly as early as the first day or as late as the fifteenth, the patient, who has no other signs of ear involvement, is seized suddenly with severe vertigo, nausea and vomiting, headaches of a mild type and loud subjective noises. He is unable to walk except in a staggering or drunken manner. In the course of twenty-four hours he becomes quite deaf to the spoken voice in the affected ear. Air conduction is much diminished or lost in the affected ear. The Weber test is lateralized in the better hearing ear if the disease is unilateral. The Rinné test is positive if both ears are involved, negative in the affected ear if but one ear is involved. Bone conduction is of normal duration if but one ear is involved, much shortened if both are affected.

PROGNOSIS.

The prognosis is bad. A few patients show some improvement in hearing under appropriate treatment used early. Most patients have had no subsequent improvement in hearing under any form of treatment. The vertigo often disappears but in some cases persists in a lesser degree for years. The subjective noises tend to become less troublesome in the course of time.

TREATMENT.

Treatment should be both preventive and curative. Preventive treatment should consist in avoiding the things that tend to cause metastasis, particularly chilling of the body. Excitement, both general and local, should be avoided. Elimination should be promoted. Intoxication by food, drink or intestinal putrefaction should be avoided. Circulatory sedatives should be administered.

Curative treatment should be directed toward the absorption of the inflammatory products in the labyrinth before they have caused permanent damage to the intralabyrinthine structures. Potassium iodid and pilocarpin are the two remedies that have been most efficient. Sudorifics, diuretics, cathartics and cardiac depressants would seem to be indicated to limit the amount of effusion into the labyrinth and to cause its absorption. Local depletion might help if used early but its effects are problematic. Inflation, aural massage and remedies that cause aural congestion are contraindicated during the early stages of the attack.

CONCLUSION.

Labyrinthine involvement in the course of mumps is a serious condition as concerns function and since it is not responsive to treatment except in the early stages it should be treated promptly and actively.

800 Davis Street.

Tuberculosis Among Negroes.—H. L. Sutherland in the *Mississippi Medical Monthly*, July, urges health officials to report the ravages of tuberculosis in the negro race, and to call the attention of influential negro men and women to it. He also urges physicians to impress on people the necessity for care in the selection of household servants.

HEMORRHAGE OF THE ADRENALS IN INFANTS.

WITH REPORT OF TWO CASES DUE TO INFECTION.*

JENNINGS C. LITZENBERG, B.Sc., M.D.
Clinical Professor of Obstetrics, University of Minnesota.
AND
S. MARX WHITE, B.Sc., M.D.
Associate Professor of Pathology, University of Minnesota
MINNEAPOLIS.

Hemorrhage of the suprarenal capsules is the most common visceral hemorrhage of the newborn. Malei,[1] Rolleston and Le Conte[2] found the surprising average of 45 per cent. of adrenal hemorrhages in the newborn in 230 autopsies, and only 1 per cent. in adults. These figures probably exaggerate the real conditions, but they illustrate the fact that suprarenal hemorrhage is common in the newborn and much more common than in adults.

Hamill[3] in 1901 wrote an exhaustive paper reporting 90 cases. We have collected an additional 29 cases, 27 from the literature and the two reported in this paper. Conclusions are drawn from these 119 cases.

CASE 1.—Baby W., born March 21, 1905, 10 p. m., in a general hospital, after normal labor; weight 7¾ pounds. Baby was normal in every way until it was 48 hours old, when it refused to nurse, was very fretful, and cried most of the time. Temperature was 106.8 F.; had repeated convulsions and passed black, melanotic material from the bowel; on the third day vomited same kind of material; also passed gas frequently and continued to pass and vomit dark blood. On the sixth day the hemorrhages from the mouth and bowels grew much worse and were of a very disagreeable odor. The baby was evidently suffering from infection; the umbilicus was thought by a consultant to be the avenue of entrance. The baby also showed signs of bronchopneumonia. On the sixth day the baby suddenly collapsed and died.

Autopsy.—March 28, 1905. (Dr. White.) The body is twenty inches long and emaciated. The navel is covered with a thin dry crust. Under the crust the tissues are dry and show no evidence of infection. The omentum does not cover the small intestines but is drawn up beneath the transverse colon. The pleural cavities and pericardium contain no excess of fluid and are free from adhesions. The tongue, pharynx, esophagus, larynx and trachea show no changes. Thymus, size of lima bean; negative. Thyroid gland negative.

Lungs: The right lung is voluminous. Its anterior margins are somewhat pale and have a feathery feeling. The dorsal half of the upper lobe and the greater portion of the lower lobe are greatly congested, dark red in color and show small areas of consolidation. Many areas are very dark reddish or brownish red in color and from these a thick, viscid, bloody substance escapes from the cut surface. The areas are completely airless, sinking in water. There are thus two varieties of lesions seen, the small areas of consolidation, and the larger, more widespread areas of hemorrhage The lower lobe of the left lung shows changes similar to those just described, but not so extensive. The contrast between the areas of consolidation and of hemorrhage is more pronounced than in the right lung. Heart, normal size; valves, negative; foramen ovale nearly closed Aorta negative. Spleen about normal size. Pulp dark in color and seems somewhat softened. Kidneys show extensive uric acid infarction in the pyramids. Cortex and capsule show no changes Ureters and bladder negative. Uterus and adnexa negative.

Adrenals: The right gland is greatly enlarged, being fully the volume of the adult organ, but shorter and thicker. It is firm and on cutting is seen to consist almost entirely of a mass of dark red, clotted blood infiltrating the organ, with traces of the adrenal cortex at the periphery. The left adrenal is nearly as large as the right and infiltrated with blood in a similar manner.

Liver: Shows some staining with bile and a moderate degree of postmortem change on its under surface where it is in contact with the colon. It is otherwise normal. Gall bladder is filled with bile. Pancreas shows no changes. Stomach is distended with partially digested blood. No ulcers or changes in the mucosa are found.

Small intestine: Shows large amounts of partially digested blood in the lumen. In the mucous membrane are a number of patches of swelling due to edema, congestion and hemorrhage, which appears to be into the mucosa and submucosa No ulcers are found.

Large intestine: There are numerous areas of swelling and hemorrhage beneath the mucosa similar to those seen in the small intestine. These areas vary from 1 to 3 or 4 mm in diameter. Appendix, 5 cm. long and free from hemorrhage or other change. Retroperitoneal and mesenteric glands do not appear swollen, nor do they show other change.

Brain and spinal cord not examined.

Microscopic Examination: The left adrenal shows marked hemorrhage and necrosis, except for narrow zones here and there just beneath the capsule. In these narrow zones the cells take the stain in quite a normal manner. The blood vessels in this region are distended with red blood cells In many places the necrosis reaches to the capsule of the organ The demarcation between living substance and the necrotic areas is sometimes quite abrupt, but, for the most part, it is noted that the parenchyma cells are undergoing degeneration, being sometimes swollen, taking eosin deeply with the nuclei showing varying grades of karyolysis, while the nuclei of the connective tissue reticulum and of the capillary walls still stain well. The areas of hemorrhage correspond, in the main, with areas of necrosis, but in places necrosis is found without hemorrhage. Even where blood is most abundant the reticulum can be traced widely separated by red blood cells and there are many round cells throughout with also many parenchyma cells in various stages of cloudy swelling and necrosis.

In the right adrenal the necrosis is more extensive than in the left, and it is rare to find even traces of living parenchyma cells beneath the capsule. The central portion of the mass consists of red blood cells and fibrin with traces of the reticulum and many round cells. An occasional polymorphonuclear leucocyte is seen. Near the capsule the reticulum becomes more readily distinguished, the nuclei more abundant, and here and there masses of large cells with nuclei in various stages of karyolysis can be seen. Just beneath the capsule there are many hyaline thrombi, which take on a yellowish color with the eosin (water soluble yellow). There is some hemorrhagic infiltration even in the capsule of the gland

Lung: There is considerable desquamation of the bronchial epithelium. The alveolar walls everywhere are greatly congested and in many places they are thickened by a round cell infiltration. In a few small areas swelling and desquamation of the cells lying in the alveoli has occurred, so that the alveoli are nearly filled. In some small areas in the upper lobe and through the greater portion of the lower lobe extensive hemorrhage has occurred. In these areas the blood is broken down into a brownish pigment in granules, the alveoli are distended with a finely granular substance taking the eosin, and the cells in the alveolar walls stain irregularly and not so well as in the areas where the alveoli contain air. In these areas the blood vessels are widely distended with blood, the pigment of which appears to be breaking down into brownish granules

Kidneys: The glomeruli are somewhat congested, but stain normally. Some of the convoluted tubules are distended with a substance which is mostly finely granular, but is hyaline in places. In some places the epithelium of the convoluted tubules is undergoing degeneration, and in most of the convoluted tubules the lumen has disappeared because of the swelling of the cells. The Henle's and collecting tubules are often widely distended with a granular hyaline material which stains a dull violet with eosin, while the neighboring red blood cells stain orange. The epithelium of these tubules is desquamating in places. The blood vessels throughout the kidney are widely distended and this is particularly true of the cortical vessels in the neighborhood of the capsular and stellate veins which are also widely distended.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908

[1] Jour. de med. de chir et de pharm., 1865, p 322.

[2] Thes de Paris, 1895

[3] Arch. Pediat., February and March, 1901

Liver. The liver shows no degenerative lesions but the vessels, especially the portal branches, are widely distended with blood.

Bacterial cultures were taken from both adrenals, heart's blood, lung, liver, spleen, kidneys, and umbilical vein. The cultures from the spleen, kidneys and umbilical vein were sterile. An organism culturely identical with *Bacterium pneumonia* (Friedländer) was found pure in both adrenals, heart's blood, lung and liver.

Pathologic Diagnosis.—1. General infection with *Bacterium pneumonia* (Friedländer). 2. Focal necrosis with extensive parenchymatous hemorrhage into both adrenals. 3. Focal pneumonia with focal hemorrhagic infiltration of lungs. 4. Hemorrhage and edema of intestinal mucosa and submucosa, with melena.

CASE 2.—Baby R., born Oct. 11, 1906, at 9:30 p. m., in the same general hospital. The presentation was a breech, but the labor was not unusually long or difficult. The baby was slightly asphyxiated but was quickly resuscitated; weight, 8½ pounds. The passages from the bowels were offensive on the first day. The baby lost a pound and a half the first two days, dejections remained offensive. There was no hemorrhage from the bowels. On the third day the breathing was very rapid and the temperature was 104 F. On the evening of the fourth day the baby's color suddenly blanched, it collapsed all at once and died as if from internal hemorrhage.

Autopsy.—(Dr. White.) The body is twenty inches in length and fairly well nourished. Postmortem rigidity moderate in degree. The naval shows no trace of cord and is covered with a thin dry crust. There is no trace of pus beneath the crust and no evidence of infection. The abdominal cavity contains about 2 drams of dark blood with some dark clots in the right half near the right kidney. The pleural cavities and the pericardial cavity contain no excess of fluid, no blood, no adhesions. The tongue, pharynx, larynx, trachea, thyroid, and esophagus are apparently normal. The thymus is 2 cm. broad, 1½ cm. from above downward, and ½ cm. in its greatest thickness; normal in location, consistency and appearance. The lungs are small and show here and there patches in which the alveoli have become distended with air. Here and there are areas which are darker in color and sink in water, evidently unexpanded portions of the lung. The heart is about normal in size, valves are negative, and the foramen ovale is nearly closed. The aorta shows no changes. The spleen is of normal size. The pulp is dark, but no changes are apparent to the naked eye.

Adrenals.[*] The region of the right adrenal shows extensive hemorrhage. On the ventral surface of the adrenal is a point of rupture from which extravasation of blood has occurred, infiltrating the pericapsular space and the right perirenal capsule, the inferior surface of the diaphragm, extending along its dorsal portion as far as the foramen for the passage of the esophagus, and infiltrating the ascending and transverse mesocolon. Nearly over the point of rupture in the ventral face of the adrenal the peritoneum has a small opening from which about 2 drams of blood has escaped into the peritoneal cavity, as already described. The right adrenal measures 3x3x2.5 cm., has assumed a nearly globular form though still concave on the lower or caudal surface where it is in contact with the kidney. On cutting the gland open, its center is a mass of partially clotted blood at the periphery of which remnants of congested and hemorrhagic adrenal substance can be seen. The left adrenal appears but slightly larger than normal and its typical outline is preserved. On cut section the medullary portion appears congested and softened and somewhat widened in places, but there is no evidence to the naked eye of hemorrhage.

The kidneys on cut section are apparently normal. The liver is normal in size and appearance. There is some bile in the gall bladder. The stomach, intestines and retroperitoneal structures show no change. The brain and spinal cord were not examined.

Microscopic Examination.—The right adrenal shows in a few places beneath the capsule small areas in which the parenchyma cells stain well and are apparently unchanged. The capillaries in such regions are distended with blood. A dense mass of blood can be seen outside the fibrous capsule of the gland. The greater portion of the gland substance shows necrosis, with either hemorrhage or marked congestion. The area of necrosis is quite sharply marked off from the areas of living cells. The cells of the parenchyma show all stages leading to necrosis with karyolysis. Near the areas of living tissue the reticulum still retains capacity for staining, but further away the nuclei of both parenchyma and reticulum fail to stain. Here and there, through the areas of hemorrhage and necrosis, considerable round cell infiltration and in many places numerous polymorphonuclear leucocytes are seen. In some small areas karyorrhexis is occurring.

In the left adrenal there is much less hemorrhage and therefore a better opportunity to study the necrosis which is occurring in foci here and there. This necrosis does not reach to the capsule at any place, but occurs in the medullary portion and may involve the zona reticularis of the cortex. The blood vessels in and about the areas of necrosis are widely distended. The demarcation is fairly sharp, in the outer layer only the parenchyma cells are affected, becoming swollen, cloudy, and the nuclei swollen and faintly staining. Deeper in, the cells of the reticulum are undergoing necrosis, but throughout there is considerable round cell infiltration and an occasional polymorphonuclear leucocyte. The blood vessels in the unaffected portions of the gland are distended with blood and in the fat about the capsule many widely distended veins and capillaries can be seen.

The kidneys microscopically appear quite normal. The capsular and stellate veins are injected. The spleen shows congestion in the pulp, but no necrosis. In some places this congestion is so pronounced as to suggest minute hemorrhages. The lung shows some catarrhal inflammation in the bronchi with desquamation of the epithelium. There are many areas of atelectasis and many unexpanded bronchi. Both in areas of atelectasis and in those containing air there is much blood in the vessels both small and large, and most of the larger vessels show small area of extravasation about them in the fibrous tissue. There is no evidence of necrosis or inflammatory infiltration in the lung. The liver shows no degenerative lesions. The umbilical artery is nearly empty and the umbilical vein shows some clotted blood without any evidence of inflammatory infiltration either in the cord or the walls of the vessel.

Bacterial cultures were taken from the right adrenal, the lung, heart's blood, liver, spleen and kidney. There was no growth in cultures from the kidney, but from each of the other organs mentioned an organism corresponding in all particulars to *Bacterium pneumoniæ* (Friedlander) was obtained in pure culture.

Pathologic Diagnosis.—1. General infection with *Bacterium pneumoniæ* (Friedländer). 2. Partial atelectasis of lungs, with small foci of hemorrhage and catarrhal bronchitis. 3. Focal necrosis of adrenal glands with congestion and small hemorrhagic foci in left, with extensive hemorrhage in right, rupting capsule and infiltrating right perirenal fatty capsule, ascending and transverse mesocolon and inferior surface of diaphragm, and rupturing into peritoneal cavity.

The hemorrhage may be microscopic or so large as to fill the whole gland, or the encysted blood may burst through the capsule into the surrounding tissues or even through the peritoneum, filling the body cavity. In one recorded case the blood burst into the liver, penetrating beneath Glisson's capsule, lifting it from the liver substance over a considerable area. In one of Hamill's cases[1] it penetrated into the tissues of the diaphragm.

---

[*] Our colleague, Dr. H. F. Robertson, recently isolated a bacterium identical in all cultural characteristics with the organisms found in these two cases, from a case of pneumonia. This organism caused hemorrhage into the adrenal in a series of four successive guinea pigs inoculated with a pure culture. Microscopic examination shows necrosis with marked congestion and hemorrhage. One of us (S. M. W.) has also found a small hemorrhage with necrosis in the adrenal of a patient dying from lobar pneumonia, from the blood and lung bacterium pneumonia was isolated.

Hemorrhages bursting through the peritoneum are not common. In Hamill's series of 90 cases there were 11, and in this series of 29 cases one of our cases and one of Oberndorfer's are the only ones which burst into the abdominal cavity, making 13 in the series of 119. There were 19 other large hemorrhages which remained encysted. If we take the bursting and encysted hemorrhages together we find that 28 per cent. of the cases should be classed as large hemorrhages. The size of the hemorrhage, however, does not always determine whether or not it is the cause of death. There were several cases in which the hemorrhages were not large, yet no other cause of death could be found. There were 22 cases in which death could be attributed to no other cause than adrenal hemorrhage and 16 others in which the adrenal hemorrhage was an important factor, if not the determining cause of death. There were but 10 cases in which the adrenal hemorrhage seemed to be of no importance.

Hemorrhage is the most common affection of the suprarenals, next to Addison's disease. One or both glands may be affected, but the right adrenal is the most common location of the hemorrhage, due, probably, to the fact that the veins of the right suprarenal empty directly into the inferior vena cava, making it more liable to share in any congestion of the vena cava than the left, which empties into the renal vein. It is also more likely to be subjected to pressure during labor because it lies between the liver and the vertebral column. In the cases in which the location of the hemorrhages was mentioned, the right gland was alone affected in 16, the left alone in 9, and both in 48 cases. The origin of the hemorrhage is generally supposed to be in the medulla, but Arnaud[4] has shown that the bleeding really takes place in the internal cortical zone, where the capillaries break under the influence of strong congestion. If the hemorrhage is large, it infiltrates the whole gland and sometimes the glandular substance is nearly all destroyed, only a small part of the cortex remaining flattened against the envelope of the capsule forming part of the wall of a cyst filled with a dark liquid or clotted blood. If the hemorrhage is limited to the cortex the bleeding is usually slight. Hengge reports one case with the hemorrhage between the cortex and the capsule of the gland, which also occurred in one of our cases. Fiedler reported two cases with fatty degeneration of the whole suprarenal except the vessels, in addition to the hemorrhages. In a few cases hemorrhage is found only with the aid of the microscope.

In one case (Still[5]) the medulla was infiltrated with blood corpuscles with no destruction of glandular tissue. Sometimes the stroma of the gland will be preserved, its cells being replaced by blood.

ETIOLOGY.

So many theories have been advanced to account for suprarenal hemorrhage that we are led to conclude that little is positively known of the etiology. However, there is one theory on which all the investigators agree, and that is that a weakness of the venous walls is responsible for the hemorrhage, but they do not agree as to the cause of this weakness. Milroy[6] and Demelin[7] believed it was a congenital weakness, while Still[5] and Lewes[8] consider that it was due to the pathologic condition of the vessels, such as fatty degeneration, which has never been found in the blood vessels, though Fiedler found it in the glandular tissue.

Mattei[1] advanced the theory that the compression of the inferior vena cava between the liver and the spine during the uterine contractions caused a damming back of the blood into the adrenal, especially during difficult labors. Hutinel[9] and Droubaix[10] agree with this theory, adding that thrombosis may also cause the damming back. Demelin[7] also supports these ideas and advances the theory that the congestion of the internal organs attendant upon the establishment of breathing in the newly born especially affects the adrenals due to their saccular structure and intimate relation to the vena cava.

Spencer[8] thought the weakness was only a normal delicacy of the vessel walls or possibly due to syphilis; he agrees with Mattei that the squeezing of the blood into the glands is an important factor, especially apt to occur in forceps operation or versions. Most of his cases required some kind of interference to complete delivery, a majority being delivered by the breech.

In this series of 119 cases eight versions are recorded, eight forceps deliveries and nine breech presentation; labor was induced once and cephalotripsy resorted to four times. Rayer[11] believed in the normal fragility of the vessels and thought the lack of firmness of the medulla a factor. Von Kirvisch[12] asserts that ligation of the cord will produce congestion and hemorrhage and prolapsed cord reported in two cases and cord around the neck reported in four cases may do the same thing. All these theories are based on the supposition of the existence of passive congestion.

Arnaud,[5] however, has proved by his extensive histologic studies with Alezais that it is not necessary to assume a morbid weakness of the vessel walls to account for the hemorrhage. The anatomic arrangement of the blood vessels in the internal cortical zone makes bleeding easy; histologically this zone belongs to the cortex, but differs from it in the reticulated arrangement of its cellular elements, and it is much more vascular, the vessels forming a chasm-like network, which Arnaud calls the vascular reticular zone because of the disposition of the epithelial rows and the predominance of capillary vessels which give, by their frequent anastomosis, a cavernous aspect. To the naked eye this zone appears as a brown line between the cortex and medulla, which is due to the vascular network filled with blood and not to pigmentation. This zone is the softest of the gland, being formed of cellular trabeculæ and of a great number of anastomosing capillaries which form by their amalgamation blood pools which break easily, not alone because of the normal delicacy of the vessels, but because they lack the support of the gland substance, the epithelial cells being scattered about in the little islands. Only the very large hemorrhages have their origin in the large efferent veins. In no case has a pathologic condition of the blood vessels been demonstrated; even in Fiedler's case of extensive fatty degeneration the vessels were not involved. Therefore, it seems that Arnaud's anatomic explanation is sufficient to account for the ease with which the vessels break, without assuming that a diseased condition of the vessel walls exist. Syphilis has been advanced by some as a

cause, but no case could be considered syphilitic unless Fiedler's two cases of fatty degeneration were.

Spencer believed that infection was an etiologic factor, and the course which many of the cases have run have been so typical of infection that the infectious origin of the trouble was advanced almost from the beginning of the investigations. Additional weight is given this theory by the fact that other hemorrhages of the new-born are caused by infection. Klebs[13] and Gaertner[14] isolated germs in hemorrhage of new-born; Merceles,[15] Weigert, Brehn,[16] Kilham,[17] Babinski[18] and Dungeen[19] confirmed these findings, some isolating one germ and some another. The fact that von Ritter was able to entirely do away with hemorrhage in three new-born at the Prague Foundling Asylum Hospital by establishing larger and more sanitary wards also lends color to the infectious origin. The fact that nearly all of the cases occurred in maternity hospitals is also circumstantial evidence in favor of infection. Both of our cases died in the same children's ward of a general hospital.

The case is further strengthened by the results of experimental inoculation of animals. Roux and Yersin[20] obtained visceral hemorrhage, including the adrenals, in guinea-pigs, pigeons and rabbits by injecting the diphtheria bacillus under the skin. Langlois and Charrin[21] obtained the same results with the bacillus pyocyaneus and also with its soluble bacterial toxin. It is of particular interest to us that Roger,[22] by inoculating guinea-pigs with the bacillus of Friedlander, the germ found in both our cases, discovered that the suprarenals were hemorrhagic and occasionally were entirely filled with blood.[1] Pilliet[23] obtained the same results by injecting the essence of cloves into rabbits and guinea-pigs, thus demonstrating that any toxemia might produce hemorrhage. Eight cases in Hamill's series, including his own three, certainly point strongly to infection as a cause of the lesion. Six cases in this series also favor an infectious origin with five others which are possibly due to that cause.

We certainly have good presumptive evidence that suprarenal hemorrhage is due to infection; unfortunately, however, the direct evidence is very meager. The cases of gangrenous varicella and bronchopneumonia can logically be considered infections. Spencer[24] also reports a positively infectious case in a child dying eighteen hours after birth of septicemia contracted in utero. The only cases in the combined series in which positive bacteriologic findings have been found are the four cases in which Riesman obtained pure cultures of the *staphylococcus aureus* and *albus* from the blood and tissues; two cases in which Hamill and Dudgeon[25] found the same germ; a case of Dudgeon's in which pure cultures of the pneumococcus were isolated, and our two cases, in which pure cultures of the Friedlander bacillus were found. Therefore, it seems that the case histories the positive proof of Klebs, Brehn, Merceles, Gaertner and others, that infection does produce hemorrhage in the newborn; and the incontrovertible experimental evidence that positive isolation of micro-organism from seven cases proves beyond question that infection is at least one of the causes of suprarenal hemorrhage.

Hamill, in summing up this phase of the subject, says: "I am inclined to believe that if complete histologic and bacteriologic studies had been made in other cases that striking evidence of a toxic origin would have been found. If such a course be applied to all future investigations it will doubtless be shown that this is not only possible, but by far the most common cause." It is interesting to note that in the four cases of this series in which Hamill's advice was followed bacteria were found.

Langmead[26] and others have thought that the hemorrhage might be due to a specific germ. This will not be found to be true because hemorrhage of suprarenals has been experimentally produced by several different germs. Six different investigators, working on hemorrhages in the newborn, found six different germs, and the idea is positively disproved by Riesman, who found the *staphylococcus aureus* and *albus,* and by Dudgeon, who found pneumococcus, and by our cases, in which the pneumobacillus of Friedlander was found. Hemorrhage may be the result of any one of a number of infections, though certain germs will be found more often than others. The port of entry has not yet been determined, and it is possible that the infection may enter by the cord, the buccal cavity, the tonsils, the pharynx, the alimentary tract or the lungs.

Analyzing the many reputed cases, we find that in reality there are only three fundamental etiologic factors: first, weakness of the vessel walls; second, passive congestion caused by difficult labors, asphyxia, convulsions or anything which would favor venous stasis; third, infection. Following infection there is an active congestion of the suprarenals resulting from the functional superactivity of the gland in an attempt, presumably, to perform its supposed antitoxin rôle in the presence of infective agents or their toxins. Sajous thinks the hemorrhage is due to insufficiency caused by paralysis of the gland tissue by toxins. The important rôle of the suprarenals naturally suggests the query: What effect has suprarenal hemorrhage on the body economy? If these glands be removed or their vessels ligated, death follows quickly. It seems probable, then, that a destructive hemorrhage, even if not large enough *per se* to cause death, may kill because of intoxication following a cessation of the suprarenal function. Just how this occurs remains for physiologists to determine.

SYMPTOMS AND DIAGNOSIS.

There are no symptoms which point directly to the adrenals, although there may be a suspicion of adrenal bleeding if a new-born baby, evidently suffering from infection, suddenly blanches and dies in collapse as if from an internal hemorrhage.

TREATMENT.

There is nothing to be said of treatment, except that improvement in asepsis in hospitals may prevent the infections which lead to hemorrhage in the new-born.

SUMMARY AND CONCLUSIONS.

1. Hemorrhage of the suprarenal capsules is more common than hemorrhage in the other viscera.

2. This is due primarily to the close relation of the adrenals to the vena cava, making congestion easy, and

[26] Lancet, London, May 28, 1904.

to the peculiar anatomic construction which favors hemorrhage.

3. A weakness of the vessel walls, either normal delicacy or pathologic alteration favors the rupture.

4. The place of election of the hemorrhage is usually in the internal cortical zone because of its vascularity and the anastomotic arrangement of the vessel.

5. The bleeding always follows active or passive congestion.

6. Passive congestion may be caused by difficult labors, obstetric operations, thrombosis, or, in short, anything that would favor venous stasis.

7. Active congestion is induced by infection or any toxemia which incites hyperemia by a superactivity of the gland.

8. The findings of the pneumobacillus of Friedlander in the two cases reported here and other bacteria in five additional cases proves beyond question that infection is a cause of adrenalin hemorrhage.

9. Death results either from loss of blood or an interference with the physiologic function of the gland.

CASES FROM LITERATURE.

Dudgeon:[25] Female, age 2 years and 8 months. On admission, very ill; temperature 101 F.; abscess on left side of neck; double otorrhea. Had frequent screaming "fits" but no convulsions. Child grew rapidly worse; temperature 103 F.; semicomatose. There was purpura on left leg.

Autopsy.—Thrombosis of the superior longitudinal sinus and the cerebral and cerebellar veins; extensive purpura; hemorrhage in left adrenal and left kidney; thymic abscess. Staphylococcus aureus and albus cultivated from the heart's blood. The left adrenal was a coffee colored mass; no hemorrhage in the surrounding tissue.

Microscopic Examination.—There were numerous hemorrhages all through the medulla of the left adrenal. The capillaries were over distended and in many places the walls of the blood vessels were ruptured. This case, though not a young infant, is reported because of the positive bacteriological findings which are so rare.

Dudgeon:[25] Female, age 1 year and 10 months. Gangrenous varicella; tubercular mesenteric glands, tuberculous ulceration of the intestines; double adrenal hemorrhage. Pure culture of pneumococcus from heart's blood and adrenal glands. The parenchymatous tissue was wholly replaced by a blood clot; the capillaries were engorged with blood.

Dudgeon:[25] Male, 14 months old. Bronchopneumonia, sudden death; double adrenal hemorrhage; other abdominal organs healthy. The whole of the adrenal medulla was composed of blood clot. The capillaries of the medulla and cortex were greatly distended.

Talbot:[27] A well nourished child, 5 months old, with severe abdominal pain, vomiting and in convulsions. Autopsy showed double adrenal hemorrhage.

Talbot:[27] Five-months-old child suddenly seized with abdominal pain, vomiting and convulsions. Temperature 101 F. Double adrenal hemorrhage.

Riviere:[28] Reported four cases all under 1 year. They had vomiting, diarrhea and fever. Death occurred within 48 hours, except in one case, in which it came within 12 hours. All showed hemorrhage of suprarenal capsules.

Little:[29] Reports the case of a child, aged 4 months, with purpuric eruption. Death occurred 24 hours after the onset of the illness with hemorrhage in both adrenals.

Little:[29] Male child, 13 months old, with diffuse purpuric eruption, convulsions, cyanosis and a fever of 108 F. just before death, which took place 24 hours after the child was taken sick. There was a large hemorrhage of the right adrenal. The left adrenal also showed numerous hemorrhages.

Steffen, quoted by Aurand:[2] Child, 7 days old, was operated on for a hare lip. Died because of diarrhea and insufficient nutrition. There was hemorrhage in both adrenals with putrid transformation.

Langmead:[26] Baby, aged 3 days. On morning of third day, the breathing became grunting in character and the child moaned; the same evening he had a convulsion and blood ran from the nose and mouth and he died in half an hour. Neck, face and head were covered with purpuric eruption. The internal organs were all normal except the lung and the suprarenals. The lower lobe of the right lung contained a large hemorrhage which could be traced up into the trachea and larynx and was evidently the source of the blood seen internally. Both suprarenals were hemorrhagic.

Langmead:[26] Boy, 2 months old. Purpuric eruption on face, chest and abdomen. At postmortem nothing was found except the purpura and suprarenal hemorrhages. They were distended with blood.

Langmead:[26] Girl, aged 7 months. Awoke screaming at 3:30 a. m.; temperature 99.2 F. At 6 p. m. the temperature was 104 F. and she was covered with an intense purpuric eruption. She died 22½ hours after her first screaming fit and 12 hours after the purpura had appeared. Postmortem there was nothing found but the purpura and hemorrhage of the adrenals which were two masses of black blood clot, nearly half the size of the kidneys themselves.

Pick:[30] One of twins. Labor very difficult. First child was breach. After three hours, second child. L. O. A.; version failed; then child was delivered with high forceps; asphyxiated but breathed after hour and a half effort at resuscitation. Born at *noon*. At 5 a. m. next day the nurse noticed second child had stopped breathing. Autopsy showed diffuse hemorrhagic discoloration in liver; right adrenal showed hemorrhage the size of a dime. The left adrenal also contained blood.

Anderson (quoted by Pick[30]): A child, 15 months old, died of suprarenal hemorrhage, which he attributed to acute toxemia, probably infectious.

Abt:[31] Reports two cases of small hemorrhages in the suprarenals incidental to more serious hemorrhages in other organs.

Hamill:[32] Reported a case dying on the seventh day from an acute infection. The right adrenal was congested and the left hemorrhagic. The suprarenal condition in this case was of minor importance and only incidental to other important findings. Cultures showed staphylococcus pyogenes aureus from heart's blood, umbilical cord and lungs.

Woolley:[33] Girl, 11 months old, had measles. Hematoma in right renal region the size of a goose egg; right adrenal embedded in mass and showed no sign of rupture. The hemorrhage did appear to have come from the gland though its source was not ascertained. The gland was slightly enlarged and firm, almost black, central vein obstructed apparently by thrombi. Microscope showed tissue of gland seemed to have been completely replaced by hemorrhage except for a few nuclei. The thrombus was a laminated fibrinous one, no bacteria.

Lieutaud:[34] Child of 15 days died after three days of convulsions. Adrenals a little larger than eggs of pigeon. In the interior is an irregular cavity containing an inky liquid.

Petit: Boy delivered with forceps; bronchopneumonia; right adrenal was transformed into a large hematic cyst.

Coleman:[35] Child, 10 months old, admitted to hospital with acute fever of a day's duration and a bullous eruption which had been present only a few hours; there were a few purpuric spots. The child died about an hour after admission; autopsy performed a few hours after. Both suprarenals showed diffuse interstitial hemorrhage. Cultures were made with negative results.

Hengge:[36] A child, weighing 2,200 gm., had, on account of a contracted pelvis, been delivered by podalic version. The child was asphyxiated but was resuscitated by Schultze's method; when thirty hours old icterus appeared and it died when three days old. Autopsy showed beside numerous ecchymoses of the pleura, pericardium and peritoneum extensive hemorrhage in both adrenals especially between the capsule and the cortex.

Oberndorfer:[37] Child died after a very difficult artificial breech delivery, was in asphyxia pallida. Autopsy, extensive bleeding in abdominal cavity through a rent 1 cm. long in capsule of the liver. Both adrenals were reddish blue tumors the size of a walnut. The microscope showed that the medulla was completely destroyed and only small fragments of the cortex were left.

Oberndorfer[37] (Case of Kleinschmidt and Romme): IIpara with contracted pelvis. The extraction of the thorax was very difficult. Schultze's methods employed for asphyxia. On the fourteenth day child died of weakness and icterus.

Autopsy.—Both suprarenals almost as large as kidneys, reddish brown in color. The microscope showed that almost all of the suprarenal substance was destroyed. The case is interesting because the child lived ten days after the hemorrhage as was shown by the age of the clot, and we are justified in concluding *that the child died from cessation of the suprarenal function and* that it lived as long as it did because not all of the gland substance was destroyed. Oberndorfer called it a case of acute Addison's disease.[38]

ABSTRACT OF DISCUSSION.

Dr. S. M. Hamill, Philadelphia: Hemorrhage into the suprarenal capsule is usually a manifestation of some form of *infection in the newly born, and,* as has been said, any one of a number of infections may produce these hemorrhages. From an extensive experience in autopsy work in the newly born, I believe that hemorrhage into the suprarenals is very common and that the evidence is sometimes microscopic instead of macroscopic. I have found some degree of hemorrhage in infections due to the streptococcus, staphylococcus, pneumococcus, *Bacillus pyocyaneus*, the colon bacillus and a micrococcus I was unable to classify. We may have infections with the pneumococcus without any evidence of pneumonia. Another striking feature about these cases is the early period of life at which the symptoms develop. The earliest manifestation in one of Dr. Litzenberg's cases was some disturbance of the stool. This has been a very early and usually the first symptom in my own cases, and suggests that the gastrointestinal tract may be the channel of infection in some cases.

Dr. Abraham Jacobi, New York: It makes me sad that there are not five times as many men and women present to

hear this paper. It is a fact that many babies die during their first week. I have seen many cases and have attributed death to meningeal and cephalic hemorrhages, which were demonstrated by the autopsies. I could account for them only on the ground of a weakness of the vessel walls and the shallowness of the impressiones digitatæ of the interior of the skull, and the injuries caused to the head during labor. Dr. Litzenberg explains many things, but there is one thing more that I want him to find out: why the infants die so suddenly. What is it that the suprarenal capsules do that these babies should die so suddenly while comparatively well? What is the influence of the suprarenal capsules on the splanchnic nerve that causes this sudden anemia and sudden death as from shock? I wish Dr. Litzenberg would communicate with two physicians in New York who have been investigating the cause of death in a woman of 45 who died very suddenly as from hemorrhage. The case was that of Dr. Bierwirth of Brooklyn, and Dr. Brooks and Dr. Ewing of New York have the case under consideration. The woman died suddenly as if from hemorrhage. The upper extremities, head and trunk were extremely anemic: all the blood was in the lower extremities. There was hemorrhage into the subcutaneous tissue, the suprarenal capsules and into the muscles, which were soft and pulp-like. Now, is there really some connection between the sudden death and hemorrhage into the suprarenal capsules? The field is fairly new and Dr. Litzenberg seems to be the one to go on with the investigation of this subject.

Dr. S. Marx White, Minneapolis: The smaller adrenal hemorrhages give a beautiful opportunity to study the relation between hemorrhage and necrosis. A little closer study will, I think, bear us out in the belief that the hemorrhage is due to the infection. There were small foci in the suprarenals that macroscopically did not indicate hemorrhage, but microscopically we found in the zona reticularis a tremendous congestion; the hemorrhage takes place in the zones of necrosis. I have seen two cases which are interesting in this connection. One was an endocarditis in a child who developed a temperature of 104 or 105 F. twenty-four hours after birth. At the autopsy, five days after birth, fibers were found at the pulmonary valve. In another case the child died on the fourth day and we found multiple foci in the lung and isolated an organism similar to, but I believe not identical with, the bacillus of diphtheria.

Dr. Jennings C. Litzenberg, Minneapolis: One of the most striking features of Case 1 was the melena, which, being due to infection, would make this case worthy of report even if there were no other conditions to attract our attention. The manifestations are indeed early; I believe that in Case I they were even earlier than I can report, on account of the nurse's failure to take the temperature on the day preceding the high temperature first recorded. I think that the extensive studies of Arnaud on the histology of the suprarenals shows definitely why the vessels break. These babies do not all die suddenly, as will be shown by the report of one of the cases collected from the literature in which there was a small hemorrhage and death was deferred, leaving us to infer that possibly a hemorrhage that is not large enough to kill by loss of blood may be sufficient to interfere with the function of the gland and cause death in that way.

Good Army Camp Sanitation.—The sanitary results accomplished by the work of the Army Medical Department at the camp of instruction near Indianapolis, recently terminated, are described by Dr. John J. Kyle in the *Indiana Medical Journal* for October. He alludes to the system of camp sanitation adopted, by which all excreta and solid garbage were completely destroyed daily by incineration and the liquid garbage disposed of by immediate evaporation or by purification in a septic tank. No serious sickness occurred, although the command averaged 6,500 men and the camping period covered over one month. Not a case of typhoid fever or dysentery originated in camp and diarrheas were rare and mild. There was an average daily sick report or less than 0.5 per cent., and it may be truthfully said there was an absolute absence of sickness due to avoidable causes.

A DISORDER DUE TO EXPOSURE TO INTENSE HEAT,

CHARACTERIZED CLINICALLY CHIEFLY BY VIOLENT MUSCULAR SPASMS AND EXCESSIVE IRRITABILITY OF THE MUSCLES. PRELIMINARY NOTE.

DAVID L. EDSALL, M.D.
PHILADELPHIA.

In 1904 I described[1] two cases that I saw in the men's wards at the Episcopal Hospital, in which remarkable muscular spasms occurred after exposure to severe heat. These patients presented none of the conditions ordinarily recognized as due to heat; there were, indeed, no symptoms of any moment, aside from the extremely striking muscular disturbance, except that both patients were slightly constipated and one had nausea and slight vomiting. The muscular spasms, however, were of a remarkable character, and in some of their details they appeared to be sufficient to distinguish the cases from other conditions of spasm that are recognized, whatever their cause.

One of the most striking features was a very conspicuous degree of fibrillary contraction, particularly in the muscles of the calf. This was of continuous occurrence, except during the frequent interruptions caused by the most marked of all the symptoms, namely, severe tonic spasms. The latter lasted for from half a minute to a minute each time they occurred and were exceedingly painful. They involved the muscles of the forearms and legs severely, but were also violent in the abdominal muscles. There was, indeed, a mild grade of continuous or nearly continuous tonic spasm of the latter muscles.

In their gross features the tonic spasms somewhat closely resembled tetany, except for the pronounced involvement of the abdominal muscles; but Chvostek's, Trousseau's, and Hoffmann's phenomena were absent. The most striking characteristic of all was the extreme irritability of the muscles to direct stimulation. While the spasms occurred spontaneously with great frequency, they were at once excited in the intervals of quiet by any attempt at voluntary use of the muscles or, frequently, by anything that led involuntarily to contraction of the muscles; and ordinary moderately deep palpation of the muscles most involved, a light tap on them, or the weakest faradic current that could be used, immediately produced locally a severe spasm, the pain of this usually leading involuntarily to contraction in other muscles, and the latter being immediately succeeded by painful and more or less general spasms in the extremities and in the abdominal wall.

The spontaneous spasms were almost entirely over within twenty-four hours or a little more, and no symptoms then remained except slight exhaustion and some muscular soreness. Slight spasm, however, could still be produced for a day or two longer by mechanical or electrical irritation, and tapping or sudden palpation still produced a very abnormal degree of fibrillary response.

The superficial reflexes were not exaggerated, and there was no Babinski phenomenon. The tendon-jerks were not excited, though the muscular contraction producing them tended in the period of greatest excitement to set up tonic spasm, as did any other muscular contraction. Sensation of all qualities (touch, pain and temperature) was normal, as were the sphincters and the pupils. The only sensory disturbance was a slight tingling in the extremities after the spasms. The respiratory and cardiac rhythms were regular, and there were no cerebral symptoms. The temperature in one patient was slightly elevated, in the other about normal. I consider the muscular contraction to be due to disorder of the muscles themselves or the terminal nerves.

---

[1] Am. Jour. Med. Sc., December, 1904.

These cases were at that time extremely puzzling to me; but, since the attacks in both instances appeared to be closely associated with exposure to a high temperature, and since in one man they had repeatedly occurred before as the result of the same apparent cause, I described them as probably due to heat. I was unable to find in medical literature any mention of heat as a cause of myospasm (except, of course, the convulsions that frequently occur in heat-stroke, as a consequence of the disorder of the central nervous system), and I could find no description of any disorder that had the remarkable clinical characteristics displayed in these cases. Therefore, I looked on them as interesting curiosities, but as of little importance beyond this.

In 1907, however, while serving in the same wards (having served, in two of the three intervening years, in the women's wards), I saw again, during the hot weather, two cases of the sort. The spasms in these were less severe and they presented no noteworthy fibrillary contractions, but they had the same remarkable muscular irritability. I reported these at the last meeting of the Association of American Physicians, and also made note of the fact that I had inquired among various physicians who see a great many men employed in occupations that entail exposure to intense heat, and that these physicians had all repeatedly seen such cases, many of which had been very severe and some even fatal. I found, too, that the men themselves who are engaged in such occupations, as well as their employers, are extremely familiar with the disorder, and state that it is very common and that they have long considered heat to be the main cause of it.

So far as I have yet gone in studying the effects of various occupations, the attacks appear to occur with a frequency that is in direct proportion to the severity of the exposure to heat and to the degree of muscular labor performed by the men; and in some kinds of work, especially that performed by certain of the iron-workers and by the men employed in the firerooms of vessels, both in the merchant service and in the navy, the number of persons that suffer in this way is surprisingly large. The cases are frequently very severe, and fatal cases occasionally occur—a very noteworthy series of deaths all told, having been related to me by various physicians, and a still larger number by the workmen, some at least of the latter cases being certainly authentic.

Since my second report on the condition, in May last, I have had another case in my own wards at the Episcopal Hospital, and have seen, for other conditions, a considerable number of men who stated that they had had such attacks. I have also seen two other patients in the course of their attacks in the wards of the Pennsylvania Hospital, in the service of Dr. James Tyson. Dr. Longcope kindly directed my attention to these latter cases and helped me greatly in conducting some special studies of them. Both of these cases were severe, one extremely so.

Further inquiry has also confirmed and enlarged my knowledge of the more or less frequent occurrence of the disorder in various occupations; and a number of medical clinicians have informed me that they have undoubtedly seen it, some of them repeatedly, but have not recognized it. I have, in fact, seen the records of several cases that had been in hospitals under various indefinite diagnoses, but that appear from the records or from subsequent questioning of the patients themselves in regard to these attacks to have been almost certainly cases of this disorder. Furthermore, it undoubtedly may occur from ordinary exposure to a high atmospheric temperature in summer. One of the most striking of my own cases developed in a man whose occupation kept him on the street. How frequent this is, however, I can not state.

The disorder appears to be, therefore, a condition that is likely to be met with occasionally in the course of a general medical experience, and one that occurs in a considerable number of occupations with sufficient frequency and severity to be of very distinct importance, especially to those whose practice lies chiefly among persons whose occupations make them particularly liable to exposure to intense heat. Nevertheless, so far as I have been able to learn by a search through most of the important text-books and monographs dealing with myospasms or with conditions due to heat, and likewise so far as I have been able to determine from a study of suggestive titles of articles under various headings, it seems to have escaped recognition in medical literature, except for a brief note by Myers[2] that I have found since my first report, and a recent paper by Elliott. In Myers' article the very frequent occurrence of more or less generalized cramps in ships' stokers is commented on, and the relation of these to either heat or alcoholism, or both, and especially to the drinking water, is suggested. The paper[3] of Elliott also records the frequent occurrence of violent muscular spasms in the men employed in the firerooms of vessels (in this instance in the navy), and reports a fatal case, with autopsy, in which no gross lesions of any importance were found except congestion of the kidneys. This latter lesion, for reasons that I shall indicate in a more extensive paper, is, I think, unquestionably secondary to the main disturbance. Elliott notes the difference between these cases and those of ordinary heat-stroke or heat-exhaustion, and believes that they constitute a type peculiar to heat cases on board ship. This, however, as I have already indicated, is a misapprehension. The cases that I reported in 1904 were both in men occupied on land, as were those that I have personally seen since: and I have, as I stated, determined that it occurs in a variety of occupations.

Several officers in the naval medical service have informed me also that some years ago the disorder was repeatedly commented on in reports to the surgeons-general from the medical officers of various ships: but that in recent years, especially since these reports from ships have been published in the Reports of the Surgeon-General, it has usually been passed over or, at most, mentioned only casually, because it is such an old story to officers. Dr. Gatewood has, however, kindly pointed out to me such a report by Beyer, in 1906, in which the general severity and the main characteristics of the spasms are described and the frequency of the occurrence of the disorder is emphasized. No better evidence of the lack of a general recognition of the existence of such a condition and of any available description of it can be found than the fact that, while a large proportion of naval medical officers with whom I have discussed the matter are very familiar with the disorder, a number of others who have had extensive experience in the navy had, by some chance, never seen it or known of its occurrence Dr Gatewood tells me, however, that he now describes it in his lectures on hygiene to the students of the Naval Medical School as the most frequent form of disorder due to heat on naval vessels

[2] Virginia Med. Semi-Monthly, Dec. 24, 1897.
[3] Mil. Surgeon, March, 1908.

I have been unable, to be sure, to secure from any of those who have seen these cases a description more detailed than that there are painful muscular spasms, which in bad cases are exceedingly severe and may even be fatal, that these are not associated with any characteristic symptoms commonly recognized as due to heat, and that tonic spasms are always present, sometimes associated with the extremely striking and more or less continuous fibrillary contractions in the intervals between the tonic spasms that I described in my first case reports These general features, however, together with the unquestionable close association with exposure to intense heat, are sufficiently peculiar and characteristic to show that the cases in the various occupations in which they occur are the same as those that I described in detail in my first paper and those seen since

The condition has such peculiar characteristics clinically as to show that it is, of course, a different disorder from heatstroke, and clearly quite different from heat prostration It appears also clinically to be different from any other recognized forms of muscular spasm In the last two cases that I have seen I was able to make some studies of metabolism, which include observations of the urinary excretion of total nitrogen, ammonia, uric acid, creatinin, chlorids, phosphates, sulphates total sulphur, calcium and magnesium. The conditions of metabolism that I found were extremely striking and essentially the same in the two cases; they have, so far as I know, no counterpart in any other conditions and are very different from any that have been observed in somewhat similar states of spasm

These studies, together with a discussion of some other less important observations that I have made regarding the pathogenesis of the disorder and a more detailed description of it and of the occupations that give rise to it so far as I can determine their number, I shall publish in a more extended paper in the *Archives of Internal Medicine* when I can get them completed At present I would mention that the condition of metabolism, together with the clinical features, indicate that it is an individual disorder, and it seems extremely probable that it is due to an acute degenerative process in the muscles Aside from the peculiar interest of this latter point in relation to this particular disorder, it is of such interest in relation to various clinical and physiologic problems in metabolism that it is highly desirable that portions of muscle be secured for purposes of study. It is largely for this reason that I publish this note I trust that I may accomplish this myself, but I hope also that those who not infrequently see these cases may do so, either by obtaining some muscle from a fatal case or by removing a portion under local anesthesia during or immediately after an attack

Clinical Notes

TRAUMATIC PNEUMOTHORAX.

W L MOSS, M D
In Charge of Research Laboratory of Phipps Dispensary Johns Hopkins Hospital
BALTIMORE

The following case seems of sufficient interest to report because of its unusual mode of production, and of a curious difficulty in diagnosis:

Patient—G H H, male, aged 49, married

Family History—Unimportant The patient's father died of measles at 25 years His mother died at 60, cause unknown His only brother died of meningitis at 25 years of age after a sickness of four days His wife is living and well Two sons, aged 20 and 11 years, are living and well Six children died in infancy at ages varying from 3 months to 4 years—one of diphtheria, one of bronchopneumonia and four of cholera infantum

Past History—Good As a child the patient had measles, whooping cough and mumps, no other sickness except an attack of "shingles" seven years ago, which kept the patient in bed for three months During this time there were repeated eruptions of herpetic vesicles over the right side and front of the lower thorax which were very profuse and discharged large quantities of 'corruption" Since this attack the skin over the affected area 'has a feeling of deadness," and it has been necessary to use a flesh brush constantly to "keep up the circulation in this part of the body "

Present Condition—The patient is five feet nine inches tall, weighs 190 pounds, and is of good habits, does not indulge in tobacco or alcohol By occupation a wholesale grocer, he leads a sedentary life and at the time of the accident was taking his first vacation in a number of years While mountain climbing he stepped on a smooth, wet rock, his feet shot out from under him and he sat down with great force The patient says that the pain caused by the fall was very intense It was located in the "small of the back," in the "pit of the stomach," and, in addition 'there was a sensation as if something had been jarred loose in the abdomen" For a few minutes he was unable to rise, but finally with the assistance of his son, he got up and made his way up a steep path back to the hotel The patient was first seen in consultation the day following his injury He was lying in bed on his back, apparently suffering great discomfort It was said that he had been unable to have a movement from his bowels or to empty his bladder since the accident It was thought that perhaps some injury to the spinal column had been received, resulting in a lower cord lesion A hasty examination revealed no disturbance of sensation in the lower extremities, rectum penis, or anywhere over the body nor was there any paralysis present After the patient had been assured that there was no injury to the spine about which he was apprehensive, he urinated spontaneously and his bowels were moved by enemata A systematic examination was now undertaken

Examination—The patient's temperature was 102, pulse 120, respiration 30 No asymmetry of chest or inequality of movements was noted Abdominal respiratory movements were well marked

Lungs Percussion note was dull over right upper front and back The note over left front and back was resonant Vocal fremitus was increased over areas of impairment On auscultation the breath sounds in right upper front were harsh and blowing, and over the middle of right back they were definitely tubular but no râles were present Auscultation of the left lung was normal

Heart The right border was not accurately defined The left border extended 2 or 3 cm to left of mammary line The sounds were distant but regular in rhythm No murmurs were heard

Hypochondrium In the right hypochondrium extending a hand's breadth above the costal margin in the mammary line and well around into the right side was an area of tympany which resembled gastric tympany. In the left hypochondrium in the region of the stomach the percussion note was flat.

Abdomen: This appeared natural; no unusual fulness; respiratory movements were good: no tenderness or masses were present and the liver could not be palpated.

Reflexes: Normal.

Special Examination: The patient complained of great pain on any movement of body. There were no contusions present. The spines of the vertebræ could be palpated; pressure over them elicited no pain. Pressure over lower ribs did not elicit crepitus or special pain. No injury to the pelvis could be made out. It was deemed unnecessary and inadvisable to make more extensive examination owing to the discomfort of the patient.

Diagnosis.—With the natural propensity for choosing the most difficult, instead of the simplest and commonest explanation of a given sign, a probable diagnosis of situs transversus was made and with difficulty left unexpressed. Feeling a strong desire to determine if a transposition of the abdominal viscera really existed, I asked permission of the attending physician to follow the case. The next day the patient was seen again. The area of tympany in the right hypochondrium persisted but there was the usual gastric tympany in the left hypochondrium which followed the normal outlines of the stomach, so that the thought of an anomalous position of the stomach and liver had to be abandoned. The patient's condition remained practically unchanged. Temperature was slightly lower but pulse and respirations remained elevated. The consolidation in right upper front and over middle of right back persisted. Râles, which had not been heard on the preceding day, were now heard. Diagnosis remained bronchopneumonia of traumatic origin. The intense pain which the patient suffered and referred vaguely to his back was ascribed to muscular strain or to some wrench given the back in falling. It remained to account for the area of tympany in the right hypochondrium. The possibilities considered were: 1, rupture of the intestine, due to the fall, with escape of gas, obliterating the liver dulness (the existence of any old adhesions about the intestine might have facilitated this result); 2, diaphragmatic hernia; 3, atony of the intestine, due to shock and consequent tympanites with obliteration of the liver dulness by the distended colon; and 4, pneumothorax. The first condition could be readily excluded, as the patient's condition at the end of forty-eight hours precluded general peritonitis. The temperature was falling, abdomen soft, respiratory movements good. Diaphragmatic hernia seemed improbable, especially as the right side of the diaphragm is protected to a considerable extent by the liver. Repeated auscultation over the tympanitic area failed to reveal any intestinal sounds. These, of course, might have been absent if the hernia had been strangulated, but the absence of signs of obstruction negatived the idea of strangulated hernia. Atony of the intestines with consequent distention, especially of the colon, might have given tympany in the right hypochondrium, but this would hardly have extended as high as a hand's breadth above the costal margin, obliterating entirely the liver dulness. The fact that there was no distention of abdomen, no marked tympanites and that there had been several movements from the bowels in the two days since the accident made it possible to exclude this condition at once. The patient was then examined with the view of determining if the condition was pneumothorax. The symptoms and signs in favor of pneumothorax were the pain, temperature, rapid pulse, and respirations, tympany, absence of vocal fremitus and breath sounds over tympanitic area; extent of the cardiac dulness to the left without anything to indicate or account for its enlargement. No tinkling râles were heard over the area of tympany; the liver could not be made out in a depressed position. The coin sound and succussion splash were not attempted on account of the discomfort caused by any examination requiring the patient to move his body. On the above grounds the diagnosis of pneumothorax was made.

Clinical Course.—It was with interest that the further course of events was watched for confirmation of this diagnosis It was predicted that in the course of a few days the air in the pleural cavity would be absorbed, the lung expand again, normal liver dulness appear, and the left border of the heart move in toward the mid-line. By about the tenth day this had taken place. The percussion note over the entire right lung was resonant, resembling that over the left lung, the resonance extending down to about the seventh rib where the liver flatness began and continued to the costal border in the mammary line. There was no longer any tubular breathing and the only abnormality to be made out on auscultation was the presence of moist râles at the bases of both lungs behind, probably due to hypostasis. The left border of the heart was well within the mammary line. During these ten days the temperature gradually fell to normal, but the pulse remained high, ranging around 100, until the area of tympany entirely disappeared from the right side. During the course of the disease another consultant was called in and found that pressure over one of the lower ribs on the left side (contralateral to the pneumothorax) caused considerable pain, but no crepitus could be made out and at no time subsequently could any callus formation be detected. It seems hardly possible that there could have been a fractured rib, but even admitting the possibility of such, its existence on the left side could scarcely have produced a right-sided pneumothorax without causing symptoms referable to the left lung as well.

It seems possible that the pneumothorax may have been produced in the following way: The patient's feet slipped out from under him and he fell to a sitting posture. The sedentary life of the patient had probably led to an atonic condition of his muscles. His reaction time was slow so that the abdominal muscles were probably relaxed when he struck the rock on which he fell. The liver, a heavy organ suspended by its coronary ligament from the diphragm, being thus unresisted, caused a sudden depression of the diaphragm. At the moment of the fall the patient "caught his breath" (closed the glottis). The tug of the liver on the diaphragm was transmitted to the lung, which, owing to the suddenness of the pull and the inability of the air to rush in and permit of complete expansion, was torn. It is not necessary to suppose that there was closure of the glottis at the moment of the fall. In the event that there was free access of air the rupture of the lung may have been due to overexpansion of the lung when the diaphragm was suddenly depressed by the liver. If old pleural adhesions existed, the tearing of the lung might have been facilitated. Inquiry into the patient's past history, however, did not reveal anything definitely indicating a cause for pleural adhesions, unless they might possibly have been associated with the attack of "shingles" seven years previously, which he described as occurring on the right side and discharging much "corruption."

GASTROSCHISIS.

CHILD BORN WITH ABDOMINAL CLEFT.

C. B. FORSYTH, M.D.
ALEXANDRIA BAY, N. Y.

The following case is reported, not for its extreme rarity, but for the fact that the child lived for a day:

Labor.—Mother, aged 17, at no time manifested any abnormality. Labor came on at the eighth month of gestation. The membranes ruptured spontaneously, emitting a large amount of yellow tenacious fluid resembling the thickened bile from an infected gall bladder. The child was presented in left occipito-anterior position, but pains were insufficient to complete labor and forceps were used.

Description of Child.—The child was normal except the abdomen, which contained a cleft three inches long with the umbilicus as its center. The peritoneum was continuous with the skin at the margins of the aperture, and extruding therefrom were the stomach and the entire small intestine. There was no pulsation in the cord and no other sign of life. In order to make the child presentable for its parents' inspection I replaced the viscera and in so doing expelled a large quantity of the same yellow amniotic fluid from the mouth and nostrils.

Subsequent History.—After suturing, I resorted to artificial respiration and was rewarded by a feeble inspiratory movement. The child soon began to breathe regularly and cried lustily; the bowels and kidneys functionated several times and the child nursed, but kept up a whining cry until it died, twenty-six hours after birth.

A CASE OF SEVERE ANEMIA, PRESENTING BLOOD FINDINGS OF A PERNICIOUS TYPE: RECOVERY.

ROLAND HAMMOND, M.D.
PROVIDENCE, R. I.

The following case is reported because of the remarkable blood findings while the patient was under observation at the hospital, and because of the interval which has elapsed—now five years—in which no relapses have appeared, and during which time the patient has been in the best of health.

I am indebted to Dr. Edmund D. Chesbro, visiting physician to the Rhode Island Hospital, for permission to report this case. The careful and complete blood examinations during 1903 are by Dr. Albert A. Barrows.

Patient.—S. McC., a carpenter, aged 46, born in Nova Scotia, entered the Rhode Island Hospital July 14, 1903, suffering from a severe anemia.

History.—Two and a half years previously he had a severe attack of diarrhea, followed by malaria lasting three months. Since then he had not felt so well as formerly and his color had not been so good, though he worked for one year after this illness. Five months before entering the hospital he had influenza and was ill for three weeks. Since then he had failed gradually in strength and at time of entering hospital complained of great weakness, dyspnea, dizziness, ringing in the ears, blurred vision and failure of eyesight, and a feeling as if hot steam were being placed on his neck and the back of his head. Two years before he was seen he had been kicked by a horse in the left lower back and side, and had a "catching" pain there at times since then. Had had "rheumatism" in the right knee twenty years ago. His habits were good and he denied venereal disease. His father and grandfather died of heart disease.

Examination.—He was a well-developed and well-nourished man of large frame with skin and conjunctivæ pale and yellow-tinged. The mucous membranes were very pale. The heart was not enlarged, but a soft, blowing, systolic murmur was heard at the apex, not transmitted. The lungs gave a few fine, crepitant râles at both bases behind. The liver and spleen were not enlarged. There was some edema of the legs. The knee-jerks were active.

Progress of the Case.—At first, as the blood became depleted, the weakness, nervous and dyspeptic symptoms and headache became marked. With improvement in the blood, however, the general condition became much better. Toward the last of his stay in the hospital he complained only of headache and dim vision. A diarrhea began a few days after admission and lasted ten days. There was some fever, the temperature at times reaching 100 to 101 F. The urine was frequently examined and was always of a normal color, specific gravity averaging 1.015, containing a very slight trace of albumin, and a rare hyaline and finely granular cast.

The details of the results of the blood examination are given in the accompanying tabulated statement. The treatment is also given in this table.

TABLE OF BLOOD FINDING IN A CASE OF SEVERE ANEMIA.

Date (1903).	Hb. per cent.	Reds.	Whites.	Stained Smear.	Medication.
July 14......	34	3.408,000	2,440	Well-marked poikilocytosis, a few megaloblasts, not typical, but transitional forms.	July 17, Fowler's sol. m. v.; Tr. Fer. Clor. m. x.
July 29......	20-25				
August 3....	20	1.172,000	4,660	Marked poikilocytosis. High color index. No marked general increase in size. No blasts seen. Occasional red cells show basophilic granules.	July 31, Fowler's sol. omitted.
August 6....	15	644.800	3,200	Marked poikilocytosis. Color index relatively high. Slight general increase in size of red cells. More megaloblasts than normoblasts.	
August 8....	15	846.000	5,200	General increase in size of reds. Color index relatively high. Occasional blasts. normoblasts more common than megaloblasts.	Iron omitted. Fowler's m. i. Aug. 9, Fowler's m. iii.
August 11....	..	690.000	6,400	Marked poikilocytosis. Relatively high color index. General increase in size of reds. Moderate number of blasts, more normoblasts than megaloblasts.	Aug. 13, Fowler's, m. viii.
August 15....	15	168.000	3,200	Marked poikilocytosis. Color index high. Slight general increase in size of reds Occasional normoblast.	Aug. 17. Fowler's, m. xii.
August 19....	20	876,000	5.800		
August 24....	35	1,088,000	3.320	Moderate poikilocytosis. General increase in size of reds. No blasts seen.	Aug. 22, Fowler's. m. xvi. Aug. 24, Fowler's, m. xviii.
September 1..	38	2.260,500	5,000		
1904. Counts made in summer of 1904 and stained smear in September, 1904, showed approximately normal blood.					
1905. May 29......	85-90	5,160,000	7,800	Red cells normal in color, size and shape. Differential white count negative.	
1908. July 10......	85	4,101,000	7,100	Red cells normal in color, size and shape. Differential white count was negative.	

This case is remarkable for the severity of the anemia with recovery. The blood examination shows the rapid variations of the disease. This case shows the third lowest red count on record, and is the only case in which the patient has lived more than a few months. Quincke reported a case in which the red cells dropped to 143.000 per c.mm. The count later rose to over 1,000.000 and the patient lived several months. Hills[1] reported a case in which the red cells reached the low count of 155.280 per c.mm. The patient lived only a few weeks. The low count in the case here reported was 168.000. and the return of the blood to normal was unusually rapid.

Skin Diseases in Children.—W. B. Brown. in the *American Journal of Obstetrics*, states that skin diseases in children differ little from those observed in adults. Children, however. not being subjected to various occupational and trade influences, do not suffer from diseases due to irritation. They seem more susceptible to pus infection: therefore. secondary infection must be borne in mind and, in fact, looked for in making a diagnosis.

Therapeutics

CARDIAC DISEASE.

A woman, aged 63, of normal weight, on Sept. 11, 1908, complained of her legs feeling weak and of breathlessness on going up stairs or walking. "The knees give out," she says. She also had dyspnea on any exertion. She looked well, her appetite and digestion were good, the bowels acted normally, the pulse was 85, rather weak and of low tension, though the arterial walls showed some hardening. The heart was slightly enlarged and the sounds were not normally loud. There was a constant rough, systolic blow at the base, which was transmitted up the aorta, showing a narrowing at the aortic orifice. The urine was negative, of rather low specific gravity, and the amount about normal. There was no edema or signs of loss of compensation other than the dyspnea.

The diagnosis was general arteriosclerosis with low blood tension due to weakness of the cardiac muscle, especially of the left ventricle, with a sclerotic condition of the aortic valves.

The treatment was to do as little walking as possible, to go up stairs only when absolutely necessary, and then slowly, and to take five drops of the tincture of strophanthus, in water, three times a day, after meals.

September 16.—The patient feels better and breathes better, and the pulse tension is greater than when last seen. Lest the heart be too much stimulated or the blood pressure too much raised in this arteriosclerotic condition, the strophanthus was reduced to four drops, in water, three times a day, after meals.

September 23.—The patient says she feels stronger, but still is breathless on going up stairs, and the pulse is again soft and weak. Her general condition is excellent. She is now to take six drops of the tincture of strophanthus, in water, three times a day, after meals.

October 12.—Her strength has now improved. She can walk better and go up stairs without much dyspnea, but she awakens in the middle of the night (and has done this for ten days) with distress, which she refers to the chest, and thinks perhaps may be due to gastric flatulence. She gasps for breath for several minutes, and feels at times, she says, "as though I would die." On her own initiative she stopped the strophanthus drops, thinking they might be causing the condition, but she found these dyspneic attacks occurred the same as when she was taking the medicine. In spite of these night attacks of asthma, as she calls it, she is stronger to walk and to go up and down stairs. Her pulse was 96 and still weak (she had stopped the strophanthus for two days). With the heart acting weakly and the blood tension low, it is impossible to tell whether this heart needs extra stimulation in the way of a strong cardiac tonic or whether vasodilation is needed to relieve the pressure ahead, even if the blood tension is low. Consequently, first to test the need of the heart, she was given a fat-free tincture of digitalis (the fat-free being less likely to disturb the stomach) in a dose of five drops, in water, three times a day, after meals.

October 14.—She had a very bad attack of asthma and cardiac depression last night. The pulse is reduced to 72, but is still weak in spite of the digitalis. Evidently the digitalis thus given is not the right treatment for her; it stimulates the heart to more active contractions, but the resistance ahead at the aortic valve is sufficient to make such increased action pernicious; consequently, the cardiac asthma or dyspnea at night was aggravated. She was now given a tablet consisting of 2 minims of the tincture of digitalis, 2 minims of the tincture of strophanthus, ¼ minim of the tincture of belladonna, and 1/200 of a grain of nitroglycerin, to take one tablet three times a day, after meals. She was also given some nitroglycerin in tablets, each 1/200 of a grain, to take when she had one of these night attacks. She was told to let this nitroglycerin tablet dissolve in the mouth and repeat it every fifteen minutes for two, three or four times if the dyspnea continued, or until there was relief. She was also told to drink but little liquid between supper and bedtime so that the blood vessels would not be over-full or the heart subjected to the necessity of circulating an increased amount of fluid. She was told to sleep with the head a little higher than was her custom, as she had been using but one small pillow. This raising of the head and shoulders often prevents attacks of cardiac asthma at night.

October 17.—The patient has had but one attack of cardiac dyspnea at night since last seen, and that was not severe. The pulse tension is better and the heart's action is stronger, and she can walk and go up and down stairs with much less disturbance; in other words, her condition is improved. Again fearing an over-digitalis or strophanthus action on this heart, which is wavering between too strong contractions and a tendency to loss of compensation from weakening of the muscle, the cardiac tonic tablet was reduced in frequency to twice a day, one after breakfast and one after (noon) dinner, for the action of the digitalis and strophanthus during the periods of day when the heart must work the hardest. She was then told to take one of the 1/200 nitroglycerin tablets regularly at bedtime, this not to be dissolved for quick, immediate action, but to be swallowed with a drink of water. The object of this was to lower the general blood pressure at a time when a higher blood pressure or increased activity of the heart was not needed, namely, at night. It should be stated that the diet has been correct from the first, viz.: meat but once a day, and simple, sensible, non-stimulating food and drink.

October 21.—She has had no attack of cardiac dyspnea since she was last seen. She feels stronger, has no cardiac pains, and is sleeping perfectly. The patient was dismissed with instructions to continue the cardiac tonic tablets for another week at the rate of two a day, and then to reduce them to once a day, and that to be taken after breakfast, and after another week to cease taking them altogether. The nitroglycerin tablets were to be continued one at night for two weeks more and then she was to cease taking them regularly, but to keep them on hand for any cardiac emergency, to be taken if there occurred at any time an attack of cardiac dyspnea.

GENERAL REMARKS.

The condition is, of course, incurable. The arteriosclerosis may progress or may remain stationary for some time. She is, of course, in danger of apoplexy. She may develop angina pectoris from sclerosis of the coronary arteries or from sudden disability of the cardiac muscle. If the aortic valve continues to narrow she will have a weakened left ventricle from myocardial degeneration, and perhaps general symptoms of loss of compensation. At present, however, the condition is stationary. It has been learned that nitroglycerin to dilate the blood vessels will relieve her symptoms. At the same time small doses of digitalis and strophanthus have improved the action of the heart. Large doses of digitalis would be dangerous as tending to cause cardiac dilatation and even death. She should never hurry or hasten to do anything, she should never drink large quantities of liquid, and she should never allow herself to become constipated. Stimulants, and even much tea and coffee are inadvisable, as is anything that overstimulates the heart or increases the blood tension.

Possibly small doses of potassium or sodium iodid, as 0.10 to 0.20 gram (2 to 3 grains) three times a day, after meals, or a small dose of thyroid, as 0.15 gram (2½ grains) given once a day, may hold the arteriosclerotic process in check. Such treatment is always justifiable and sensible.

FOUL BREATH.

While this is a very frequent, it is also a preventable condition; hence it is rarely excusable for a person having once discovered that the breath is objectionably offensive to others to neglect its prevention. Perhaps the most frequent cause pertains to the teeth. There may be cavities, or there may simply be a lack of cleanliness from an insufficient use of the tooth brush and proper tooth powders, tooth pastes or mouth washes. It is also necessary, when one is alone, to remove with a toothpick particles of food which may have become fixed between closely-set teeth. All cavities should be filled and tartar deposits should be regularly removed, not only because of their likelihood to cause disagreeable odor to the breath, but of the possibility of allowing germs to develop and be swallowed. If the stomach is not in a healthy condition and the gastric juice not normal, such germs may not be killed. The proper tooth powder should be determined by the ease with which the teeth are cleaned, some requiring more friction in the powder, and others requiring more soap. The choice of the powder and the frequency with which the teeth should be brushed is determined by the results. They must be kept clean, and the cleaning must be done at least twice a day, morning and at bedtime.

If there is any tendency to alveolitis, or if purulent alveolitis is present, then antiseptic, followed by alkaline, mouth washes should be frequently used until the condition is cured, but if it tends to recur, then such mouth washes should be used once a day, continuously. For a time weak peroxid of hydrogen solutions are beneficial, especially if the acid, which is formed after its oxidizing action, is quickly washed away with an alkaline solution. If the gums are spongy a 5 per cent. solution of potassium chlorate makes an efficient mouth wash. One of the best local astringents and local antiseptics is a dilute solution (perhaps one part to five) of alcohol in water.

The teeth not being the cause of the odor of the breath, the tonsils should be examined, and not infrequently little calcareous deposits will be found in one or more crypts, or there may be a pocket of caseous deposit back of the tonsil. These should, of course, be removed and the crypts treated with some antiseptic solution and a cleansing antiseptic gargle given.

Another frequent cause of bad breath is postnasal or nasopharyngeal catarrh. If this is a chronic condition the treatment is tedious, and unless the patient thoroughly cooperates, results will be unsatisfactory. The proper treatment of nasal and nasopharyngeal catarrh can only be determined by a study of the individual condition. A warm cleansing solution is, of course, always important and the frequency of its use can only be determined by the rapidity with which the secretion forms deposits.

In atrophic rhinitis the odor is terrible, and, unfortunately, the condition is generally incurable; but there is absolutely no excuse for such a patient polluting the atmosphere of the rooms in which he works or lives. The odor can be prevented by the proper use of mild antiseptic and cleansing solutions.

Wylie, in the *West London Medical Journal,* April, 1908, says that it is useless to expect to clear away fetid accumulations in the nose and nasopharynx with antiseptic solutions, as they do not possess the power of dissolving mucin and albumin, the principal constituents of the crusts. He believes the best solvent is a 1 per cent. solution of sodium sulphate or a 0.5 per cent. solution of sodium borate, in water. He would douche the nose thoroughly with this solution (which must be warmed) until the "crusts and caseous matter" have been removed; then antiseptic solutions may be employed by means of sprays. If the mucous membrane is not degenerated and is still sensitive, he would spray with "liquid paraffin containing menthol, oil of cinnamon, or eucalyptus," but if the fetor is great, and in bad cases of atrophic rhinitis where the mucous membrane is not very sensitive, he would sparingly use Dobell's solution. This solution is as follows:

℞.	gm. or c.c.		
Phenolis	1		m. xv
Sodii bicarbonatis	3		
Sodii boratis	3	or	āā, gr. xlv
Glycerini	10		fl.ʒiiss
Aquæ, ad	200		ad, fl.℥vii

M. et Sig.: Use as an antiseptic gargle or as a nasal antiseptic spray.

Wylie attempts to restore healthy secretions by gentle stimulation with a snuff composed of boric acid and attar of roses, but if the disease is atrophic in type and the secretion scanty he uses a very weak formaldehyd solution as a nasal douche. He wisely cautions against carelessness in nasal douching. The very slightest excess of pressure should never be allowed, else the liquid or secretion may be forced into a eustachian canal and middle-ear inflammation follow. He also suggests a nasal douche of "boiled and decanted sea water."

He removes hard crusts painlessly by first subjecting the nasal passages to inhalations of steam, camphor being added to the hot water as a stimulant.

Other causes of disagreeable breath are constipation and dyspepsia. The cause of these conditions should be treated, and as the tongue becomes clean and the pharynx less congested the breath will become better.

Laryngeal and bronchial inflammations and catarrhs, of course, are other causes of bad breath. If the condition is acute or subacute, it can soon be improved by proper treatment. If the condition is a chronic one, mild antiseptic inhalations will largely prevent the fetid condition.

℞.	c.c.		
Creasoti	1		m. xviii
Olei pini silvestris	10	or	fl. ʒiii
Tincturæ benzoini compositæ, ad	100		ad, fl. ℥iv

M. et Sig.: To inhale a teaspoonful from boiling water one, two, or three times a day.

The bad breath of acutely sick patients, as with typhoid fever, pneumonia, or other serious illness, can be minimized by the proper care of the mouth, tongue and teeth by the nurse. Even the bad breath of patients suffering from incurable disease may be bettered by good advice and simple local care.

SATURDAY, DECEMBER 5, 1908.

EXPERIMENTAL CHEMOTHERAPY.

The recent address by Professor Ehrlich before the German Dermatological Association contains so much that is novel and suggestive that a statement of the chief points can not but awaken interest. While the specific curative action of mercury and iodid of potassium in syphilis is unquestioned, yet it is entirely unknown in what way they act. In order to throw more light on this phase of therapeutic action it is necessary to break away from the beaten paths of investigation and to start out on new lines. As long as twenty-five years ago Ehrlich showed that when a certain coloring matter is injected into a living animal it may stain only certain tissues, e. g., those of the nervous system, indicating that there is a peculiar avidity on the part of this particular tissue for the stain. Hence grew the side-chain theory which has proved to be of such tremendous importance in immunologic investigation, and the essential point in this theory is that certain substances may act on a tissue, or cell, or parasite, only when it is taken up by the body acted on. Ehrlich states that to understand the relation between the chemical composition of a remedial agent and its action it is necessary to determine how the substance is distributed throughout the body and where it is anchored and causes its special effects. We see that Ehrlich here is building still further on his lateral chain hypothesis, and we now turn to this recent work with trypanosomes.

When it became clear that sleeping sickness and other forms of trypanosomiasis were not curable by serum therapy, search was started for chemical substances to destroy the parasite in the body. The difficulty is to find chemical substances that will destroy the parasite and at the same time cause no injury to the host. Under the name atoxyl (sodium aminophenyl arsenate) a form of arsenic was introduced hopefully a few years ago, but it did not give satisfactory results in trypanosomiasis because the trypanosomes, especially in animals, soon become immune to its action. In other words, as Ehrlich would say, the microbes lost certain of their chemoreceptors so that the atoxyl no longer was bound. Recently Ehrlich and his coworkers have succeeded in producing an enormous number of new combinations and variations of this substance, and these they have tested biologically on a large scale. Toxic as well as non-toxic derivatives have been obtained, some being, for instance, 1,500 times as poisonous as others. Thus there is one substance that causes such changes in the brain or ear of mice as to turn them into the so-called dancing mice; others cause icterus or diarrhea; others renal lesions—different combinations producing different lesions. On testing the substances on animals with trypanosomiasis it was found that one (acetylarsanil acid) would cure mice even if given only a few hours before death occurred in the controls. But this substance did not seem to act directly on the parasite, but either by being changed itself within the body or because it causes trypanosomicidal substances to form in the body. Ehrlich reasoned that the effect might be owing to reduction products as a result of the reducing power of the animal tissues, and by reduction experiments outside the body, substances of extraordinary action have been obtained. Whereas a 5 per cent. solution of the original acid did not have any influence on trypanosomes in the test-tube, new substances have been obtained solutions of which in concentration of 1 to 100,000 kill the parasites at once and in thirty minutes when diluted 1 to 1,000,000. Hence arsanil acid probably does not act as such in the body but by virtue of its reduction products.

As stated in the foregoing, Ehrlich postulates that the protoplasm of cells contains certain chemical groups which anchor chemicals in the same way as bacterial poisons are assumed to be fixed to the cell, and he now believes that he has found a substance which has an intense avidity for trypanosomes and which is not very toxic. Indeed, it cures advanced trypanosome infections in mice and rabbits even after a single injection, thus reaching the same ideal of direct therapeutic effect that so far has been achieved only by certain antitoxic sera. While these results do not apply directly to human beings they certainly are full of promise, and no one can say that some day great enrichment of therapeutic resources may not come from this splendid work.

HONEST AND DISHONEST BIBLIOGRAPHIC WORK.

Not long before his death Virchow wrote a scathing criticism of some features of current German medical literature. He especially criticized the pretense to erudition shown in the reproduction of quotations and bibliographies, and his counsel to his compatriots to "verify your references" came as a sort of shock to those of us who had been prepared to accept everything with the "made in Germany" label as authentic and authoritative. Some of us, of course, were well aware of the facts; we have seen misprints carried from one bibliography to another, cases duplicated and other errors vitiating a considerable portion of the literature of a disorder or an operation in certain instances. Of course, the Germans were not the only sinners, but their traditional thoroughness was sometimes only a fiction—a sciolistic pretense
